SAN FRANCISCO, SATURDAY, JANUARY 2, 1875.

VOLUME XXX
Number 1.

Improved Current Water Wheel.

The means of utilizing the power afforded by the current of a river, where sufficient fall cannot be obtained to run a turbine wheel successfully, have been brought to comparative perfection within a few years by the improvements which have been made in this class of devices. Necessarily, where even the best form of current wheel is used, the application of the power of the stream is made in but an imperfect degree as regards economy, a large proportion of it running to waste, and only the effect of the water directly in contact with

the wheel being gained; but as no other expense than that of constructing and setting the wheel is incurred, the investment is often a very profitable one. To obtain all the power which the volume of water in the stream would afford would require the building of a dam, and consequently the employment of capital, frequently to a very liberal extent, in securing the primary facilities for doing business; and where this capital is not at command, or a large business is not contemplated, an ample return may be realized on a moderate investment by putting in a current wheel of the most approved construction. Such a wheel is illustrated in the accompanying engraving, which shows a basin made in the bank at right angles with the stream, its sides being protected by planking, for which stone may be substituted, if cheaper or more convenient. In this basin floats the raft which carries the wheel, the frame of the raft being so made as to balance the weight of the wheel. The basin or slip is dug deep enough to float the raft and wheel at low water, and extends into the bank a distance equal to the length of the whole apparatus, which may thus be drawn back entirely out of the current. This is a point of special value, as by means of this arrangement the wheel and raft can be withdrawn out of reach of drift wood and thus be protected from injury when the stream is swollen by heavy rain or melting snows.

The wheel, which is an undershot, is shown projecting into the current and in operation, its motion being communicated through the gearing A, to the horizontal shaft B. On this shaft slides a loose pulley, C, having on the left hand side of its hub an annular recess and a clutch, by which, when desired, it is engaged with the shaft B. The annular recess receives one end of the shipper lever D, the other end of which is made fast on the bank, and by means of a hinge the lever is rendered adaptable to the position of the raft at any stage of water. The shaft E, which is rotated by a wheel at one end as shown, has chains wound around it, leading to the opposite ends of the raft; and thus, by turning the wheel toward the bank, the raft is drawn in, while by turning in the other direction it is moved out into the stream. When the raft is run out, the wheel is held in position by a pawl which drops into a recess in the shaft E. The rollers F, on the sides of the raft, only one of which is shown in the engraving, facilitate the moving of the raft by their contact with the plank-

ing of the basin, preventing the friction which would result from the raft being forced by the current against the side of the slip.

It will be seen that when the raft is moved out, the lever D will draw the clutch into action, and the motion of the shaft B, received from the water wheel, will be transmitted through the loose pulley, C, and its belt to the machinery of the mill. On the other hand, when the raft is drawn in, the lever D, remaining rigid, will push the parts of the clutch asunder and the loose pulley will cease to turn. By this arrangement, the same appliances by which the raft is moved in and out serve to regulate the transmission of power and the starting and stopping of the machinery.

More Rain Wanted.

The immediate want of rain is not urgent, according to such information as we can obtain from correspondents, exchanges and other sources, but serious apprehensions are looming up in connection with the prospect of a dry winter which many now predict. We have no sympathy with croakers; and one of the regrets growing out of the present unpropitious aspect of the season, is a sort of mortification at the satisfaction which these evil prophets manifest over the seeming truthfulness of their pre-

Rosita Mining District.

The Rosita or Hardscrabble mining district is located in the southwestern part of Fremont county, Colorado, and is one of the most accessible silver mining districts in Southern Colorado, being fifty miles southwest from Pueblo, and 30 miles north of Cañon City. The communication with both places is made over excellent wagon roads.

W. H. Holmes kindly sends us the following information concerning this district: The mining town of Rosita is the center of the rich-

est mines that cover the surrounding hills in every direction. It has a population of 500—mostly miners—and contains three hotels, four stores, school and "meeting house." It is a wide awake, growing town and one of the most orderly and respectable mining communities in the Territory. Rosita is at an altitude of 8600 feet above the level of the sea, being situated on the southwestern slope of the Wet mountain range, and protected by the mountains from the prevailing winds. The winters here are mild, the temperature corresponding with that of Denver, 150 miles farther north. Mining can be prosecuted here during the entire winter.

The first work on these mines began about two years ago. Since that time the work of prospecting and developing these mines has gone steadily on, though for the want of capital the development of some of the best mines has progressed slowly. Capital for the development of these mines and the erection of reduction works at this place for the treatment of the lower grade ores is greatly needed. The best authorities on mines in the Territory have stated that the precious metals here will undoubtedly develop it into one of the richest silver mining districts in Colorado. Prof. Hayden and Lieutenant Wheeler's parties visited this district during the summers of 1873 and '74, and give the most favorable report of them.

The veins throughout the district are well defined, and show high grade silver ore, specimen assays running up from \$35 to \$15,000 per ton, notwithstanding that 100 feet is the greatest depth to which any shaft has been sunk. Several mines are now shipping ore to Black Hawk, Golden and other points that sells for \$300 to \$400 per ton. It is reported that some of it sells for a much higher sum.

JOE SEALEY, Deputy County Surveyor for Inyo county, is engaged in chaining and mapping a road from Panamint via Darwin city and New Coso, to the point of connection with the Cerro Gordo and Lone Pine road at Swansea.

The improvements now going forward at the Savage hoisting works are being pushed to completion with all speed. They are of a substantial character, like all the improvements made about the mines of late years.

Within the past few weeks \$100,000 has been invested in the mines of Bingham, Utah, by California parties.

MCCARTY'S CURRENT WATER WHEEL.

Any additional information concerning this improvement may be obtained of the inventor and patentee, Mr. M. McCarty, Pueblo, Col.

THE SACRAMENTO "UNION" SOLD.—The Sacramento Union, according to previous announcement, was sold to the highest bidder, in the street in front of that office, on Monday last. There were but two bidders Messrs. Larkin, (who was the party desiring to sell out) and Mr. Morrill, who represented the remaining interest. The first offer was \$50,000, which was followed by \$60,000; \$62,500 and \$65,000 at which latter price it was knocked down to Morrill, who represented the majority interest in the proprietorship. Hence the paper will be continued without any change in the manner or tone of its management.

WISCONSIN is the latest location of our Eastern mining excitement. Two California miners are reported as having struck a quartz lead there which assays \$1,700 to the ton. Those two California miners may fool some of the Wisconsin people into buying the whole thing on the basis of \$1,700 per ton, and do well with the claim.

It will be remembered that on the appearance of the first rains of the season, which were unusually early and copious, fears were entertained that they would be followed by a dry winter; and at the present time there is, it must be confessed, too near a prospect of those fears being realized.

While we do not believe in gauging our operations or allowing our feelings to be swayed by the predictions of those who are continually prophesying evil, we are not disposed to close our eyes to anything that is so near an approach to disaster as the present scarcity of rain renders imminent. We might as well face the music at once, as to wait until the din becomes confusing.

In many localities in the mining districts, the weather is too cold to work anyhow. In other places they were not quite ready at the time of the last storm; but have their claims all prepared to go ahead on now. Most of the miners are hopeful of a good water season, and a plentiful harvest of yellow dust. It is to be hoped that a good supply of snow will store itself up on the mountains for summer use, so that the ditches and pipes will run full until late in the season.

The Big Mill.

About three months ago the Consolidated Virginia mine, on the Comstock, commenced the erection, in connection with their hoisting works, of an immense steam mill, for the reduction of silver ore. It is the largest steam silver mill on the coast, and from the completeness of its arrangements and its conveniences for handling and reducing ores, it will be found to excel more in capacity than in size and dimensions and the number of the stamps. The *Virginia Independent*, in describing this big mill, says: The ground where the mill stands is admirably adapted to its present uses. The site is to the north and east of the hoisting works, and between the two the descent is such that the ore can be run from the level of the surface of the hoisting works, and reach the mill at its very pinnacle. The ground covered by the mill also descends very rapidly to the east, so that the ore falls naturally to the stamps; from the stamps, by distributing sluices, the pulp drops to the tanks, from the tanks to the pans, and so on down by a gradual descent to the agitator room. Some idea of

The Dimensions of the Mill

May be gained from the following particulars: The battery building is 110 feet long, by 48 feet wide; the pan building is 195 feet long by 92 feet wide; the engine room is 58 feet by 92 feet, and the retort house 25 feet by 60 feet, the whole covering over 26,000 square feet of ground. Besides these buildings there is an office 20 by 30 feet, fronting on G street.

The Engine

Is a compound condensing, or low pressure engine, of 600 horse power, with cylinders 24 by 48 and 48 by 48 inches respectively. The steam is admitted into the 24 by 48 cylinder and cut off at the half stroke. It is then taken into the expansion cylinder, which is 48 by 48, and contains four times the cubical contents of the smaller one, and thus an expansion of eight times is gained. After leaving the expansion cylinder the steam exhausts into the condenser. This gives the vacuum power or the power resulting from the atmospheric pressure at this altitude in addition to the expansive power of the steam.

The Engine Shaft

Is 14 inches in diameter, and carries a band wheel 18 feet in diameter, weighing 33,000 pounds, which drives the battery part of the works. This shaft itself weighs 15,000 pounds, and the approximate weight of the whole engine is 100,000 pounds, or 50 tons. The foundation of this ponderous piece of machinery contains 450 cubic yards of masonry, laid in cement, and weighs 600 tons. This engine shaft is coupled to an extension 11 inches in diameter, which drives the amalgamating part of the works.

The Boilers, Etc.

The boilers which supply this monstrous motive power with steam, consist of four pairs, 54 inches by 16 feet, so arranged as to run a single pair at a time, or all together. The smoke-stacks are 42 inches in diameter, and stand 90 feet from the ground. There are also, in connection with the boilers, two steam pumps, for feed and fire purposes; to these a water-hose is constantly attached and ready for use in case of fire. The roof of the engine room rises to the height of 50 feet; the western earth or embankment wall is 22 feet high, built of brown trachyte rock, and, with the other embankment walls, contains 4,000 perch of stone. We will now commence and trace

The Ore from the Mine through the Mill.

The mill is connected with the hoisting works by means of a covered trestlework, 44 feet in height at the mill end. The same cars used in the mine will be run in trains by mule power from the mine, 278 feet to the mill. The trains will consist of from six to ten cars. It will take a car-load every five minutes to empty the demands of the mill. These cars are dumped into shutes, one on each side the center, from which the fine ore sifts into the ore bins below. The part of the ore first dumped is carried back from the center by shutes, and thus becomes equally distributed into the feed bins. From the feed bins the ore is taken by Tulloch's self-feeders and given to the batteries as it is required.

The Batteries

Are driven from a counter shaft propelled by the large band wheel below, the connection with which is made by a belt 24 inches wide and 160 feet long. From this counter shaft the batteries are driven by 14-inch belts, 60 feet long. The batteries are run in sets of 10 stamps each, and clutches are so arranged as to stop any ten without interfering with the working of the other machinery. The batteries consist of 60 stamps of 800 pounds each. The mortars are so arranged as not to interfere with putting shoes and dies into the batteries, as they discharge at one side and are two nearly together instead of separately and in the center. From each division of 30 stamps there are

Distributing Sluices

Which convey the pulp into the settling tanks. From the tanks it is shoveled out upon the platform in front of the pans. There are 16 pans on each side. These are flat-bottomed, 3 feet in diameter and calculated to hold about two tons each. The pans have steam bottoms,

and are arranged to admit live steam into the pulp or under the bottom. There is a settler to each pair of pans, making 8 on each side. These are 9 feet in diameter and 3 feet deep. From the 15 settlers the pulp is discharged into four agitators, and these discharge in turn into the tail sluice which is placed at the end of all the other appliances. The heavy stuff in the agitators will be cleaned out twice every 24 hours and subjected to further working by four more pans and two settlers placed in the agitator room.

The Quicksilver

Tank is placed in the store-room under the ore bins, and will come down pipes to the distributing tanks in the pan-room. From these tanks it will be distributed through pipes to the charging bowls of the pans. After passing through the pans and settlers it is discharged from each settler direct into each strainer. A pipe leads from the bottom of each strainer to the main receiving tank, which is placed below everything and in the center of the pan-room to catch all; and from that it is pumped up into the main distributing reservoir again. There are two of these reservoirs—one on each side.

The Amalgam

Remains in the strainers, and is taken by an amalgam car, holding about twenty tons, which runs through the center of the pan building to the retort room. The same car takes retorted silver back into the mill circulation. Each pan and settler can be stopped without interfering with the other machinery. Each row of pans and battery has a traveling tackle for convenience of handling the stamps and pan millers. The strainers are provided with locks and covers for protecting the amalgam.

The Retort Room

Is built of brick and contains four retorts, each of which is calculated to hold 2,000 pounds. These are so arranged that any one or more of them can be run. The flues lead into a brick chimney fifty feet in height. Back of the reduction works is a

Cooling Reservoir

About 200 feet square, where the water from the condenser can radiate its heat and attain the required temperature to be used again. And the controlling mind which mastered all these details, and so admirably arranged everything with an eye to convenience and business is

W. H. Patton, Designer and Superintending Engineer

At the works. He it is who has planned and arranged it all. He is the master designer of all the vast complications of machinery, all of which has been constructed according to his directions. The arrangements are ample, yet compact. There is no waste room and no more room needed. There is no superfluous machinery, and none wanted which is not in place. Everything is economized, yet of the best material and put down to stay. As to the quality of materials used, no expense has been spared to get the best. What was needed was got. The cost of the mill is about \$250,000, including the grading. A few years ago it would have cost half a million. This economy could not have been secured, except Mr. Patton had known just exactly what was wanted, and how much of everything would be needed.

The work will be so far progressed that steam will be got up about Christmas, and the month of January will see this largest and best silver mill in successful operation. Many a whole town on the coast is maintained by the patronage of a much smaller institution.

Mining Theories.

Recent developments have set those persons who have their peculiar theories about the course of the Comstock lode all at sea. Millions of dollars have been expended in tracing the ledge, and millions more will be spent in finding its direction north and south. The many-ledge theory which was much in vogue in early days, and on which many important suits were decided, but which subsequently gave way to the one-ledge theory, is being adopted again. Others take the ground that several ledges on the surface come together like the leaves of a book thousands of feet below. Some think that at the divide the Comstock breaks into three branches, one extending through American flat, one down through Gold hill and another further east. Experts from Freiberg, and miners from Mexico and Peru, have given their opinions on these points on the witness stand, and been subjected to a rigid examination, but after the cases were submitted the jury knew about as much about the question as they did about the volcano in the moon. In scarcely an instance has actual development shown any of the theories upon which men staked their reputations, and sometimes lost their lives, to have been correct. The thousand abandoned prospecting shafts and tunnels that honeycomb the sides of Mount Davidson, Cedar hill and the surrounding country for miles, speak for themselves, and show the uncertainty of mining. What has been shown by prospecting is known, and nothing more. Who knows but that far east and west of the present developments rich bonanzas exist, which will hereafter be discovered? Theorizing on croppings and the course of ledges is about played out, and experienced mining superintendents no longer place confidence in what is not in sight.—*Virginia Chronicle*.

The Iowa Hill Canal,

A correspondent writes to the *Placer Argus* giving an account of the season's work on the Iowa Hill canal, from which we make the following extracts: The right of route is one of the best in the State; the cost of construction so far, for so large a work, taking as a basis of comparison the figures given in Langley's Pacific Coast Directory of all the canals in the country, amounting together to over 6,000 miles, is I am safe in saying, far less than any similar work in the State; the water shed is simply enormous; the expense of repairs, and attendance, from the favorable character of country it passes through, except the upper end, will be trifling; the territory it commands is inexhaustible in wealth and extent, for by a judicious system of reservoirs, which is the cheapest process in the end, the water supply, without going farther than Sailor and New York cañons, can be delivered over the whole of the upper portion of the county, from Iowa hill to Michigan bluffs, in abundance, for seven or eight months in the year, and that is long enough. I might with advantage mention several more salient points this great work possesses over its competitors in other parts of the State, only I am afraid of being too lengthy.

As a matter of course, those at a distance having an interest in the matter, either peculiarly or otherwise, will like to hear about the progress of the work this season. I believe I may say it has been satisfactory in every way. I have already expressed through the columns of a San Francisco paper the respect I felt for the leading men of the company for the vast amount of work they have accomplished during the first season under the most pressing difficulties. Financially, the present season has been equally harassing; but with true California pluck, they kept economically and steadily at work, and the results as they stand to-day, rather increase my admiration than otherwise. The hardest part of their labors is over; the remainder is easy. There are now 26 miles of canal, seven feet on the bottom, with reservoir, waste gates, and flumes to Tadpole lake, complete. The main ditch in its original capacity, stops about four miles from town, and is hence divided into two branches, somewhat smaller, going respectively to Iowa and Wisconsin hills, and covering all the claims on either side of Indian cañon. Some of these claims are now fixing up on an extensive scale, having in all cases not less than 500 feet pressure.

The main reservoir eight miles from town, has been raised from 32 to 50 feet, widened 10 feet and extended from hill to hill bounding the valley, making the total length of wall 286 yards. The amount of dirt put in the reservoir this season by 10 Chinamen and four horses was 17,000 cubic yards, besides doing 34 days outside work in the neighborhood. Since the horses were drawn off on account of storms, a railroad has been put on the entire length of the reservoir, and two large cars will be kept running all winter. The track rises the wall an additional two feet, so that the entire available capacity of the reservoir is now from 48 to 50 feet of water in depth at the main trunk, 286 yards in width, with an overflow of somewhat over 100 acres. Basing my calculations upon the amount of water discharged to Judge Spears claim, for six consecutive weeks, last season without any supply coming in, I make the cash value of such filling about \$7,500. Now if as some contend, it can be filled four times in an ordinary season, we see at once the respectable sum the company will realize this winter; but whether it can be filled four times or not, for I admit there is a difference of opinion upon the matter, one thing is certain, the company will realize enough to place them beyond all external pressure in the future. This I mention as a final victory secured beyond controversy.

The demand for water this season is about 5,000 inches a day, but the company will not attempt to supply more than 3,000. Can they really supply this large amount? Let us see. On the first of the current month, there were 25 feet of water in the reservoir, with a daily supply of 400 inches, besides 2,000 inches turned off at Tadpole, owing to a break in the flume at that place, but which will be repaired before you receive this letter. Here then in solving the question of supply one finds this startling fact; in two seasons' work the company is in a position on the 1st of December, 1874, to supply 2,400 inches a day, a fact unprecedented in the history of this divide, and I believe unlooked for by the most sanguine. Of course this supply at so early a period, will be greatly reduced, perhaps stopped altogether when frost and snow set in at Tadpole. Well, never mind that, what we want to get at is the actual and possible supply, that is, what can really be done under ordinary circumstances. It is a money calculation, and must be free from all bosh and exaggeration. In this spirit I hold the facts as we find them to-day, settle the question of supply in the affirmative, and just a little more; they silence forever the miserable croakers who in turn, are glad enough to take the pay and feed of the company when they can get it, but who in turn, foolish and ungrateful to the extreme, can never give them a well earned word of praise or encouragement.

From the reservoir to the Secret house, the canal has been cleaned and widened, and put in perfect condition, except in one place, which the early break in the weather prevented being finished thoroughly. These few rods however, will not materially interfere. It would simply have been better if the cement at this place

could have been cut down a little. From the Secret house to Tadpole, a fine substantial flume one mile and a half long, six feet and a half wide, and five feet deep, round an almost inaccessible point of rocks has been built, and is, perhaps, the most creditable portion of the whole work. It has certainly been the most tedious and difficult. This ends the season's work. Next season all that is required will be to reach Sailor canyon, if possible, and to build a couple of reservoirs. That done, and Placer county may be proud of the Iowa Hill canal, for in every respect, it will be a magnificent property, and reflect the highest credit, both as regards the time and cost of construction, upon all who have been entrusted with its management.

Coso—The New District.

We take the following from the *Inyo Independent*: After a close inquiry as to the real facts in the case, and careful consideration of the united testimony of a great many of our citizens who have visited and examined the recent discoveries in the new Coso district, we are forced to the conclusion that the mines are simply enormous in their extent and value. Their discovery in the month of October last, was brought about as follows: Prof. Wm. D. Brown, a gentleman having large experience in the study of mines and minerals—and who, as early as 1867 made an examination of the Cerro Gordo mines as an expert—concluded, since the discovery of Panamint, that the country between Cerro Gordo and Panamint was rich in mineral wealth. Leaving San Francisco early in October, well prepared for a thorough prospect of that country, accompanied by his brother, he arrived at Coso late in that month. There he found specimens of lead ores in the possession of native Californians, but could get no clue to the locality from whence they came. He immediately ascended the highest point near by, and took a view of the surrounding country, and following his judgment, proceeded at once to the mountain in which the rich mines have since been opened. Here he found the "Promontorio" mine, with a notice of location upon it by "Rafael Cuervo." He then made a careful examination of the ores and formation, and found the hills composed of lime rock on the west and porphyry on the east, and concluded that mineral must lay at the juncture of the two formations. Following and tracing he soon discovered some wonderful deposits of mineral, and the "New York" location was at once made, which produces very rich carbonate ores. To say that the mine is forty feet in width, and traceable 2,000 feet, sounds wild, but comes near the truth. Following further these formations the Browns made other locations of carbonate mines, almost duplicating the New York—i. e., the "St. Louis," the "Grand" and others. The latter, located on the 3d of November, cleaves a bill and lays between the limestone and porphyry; it is traceable for about 3,000 feet, and in many places is 30 feet in width. Bentura Beltran, an old and well known prospector, early in November, located a truly wonderful mass of wealth, its general description being the same as the Promontorio, New York and Grand ledges.

Besides this class of mines, there has also been discovered and located some remarkably rich fissure veins. Cropping out bold and distinctly, these veins cleave both the porphyry and limestone. They bear chloride and sulphuret ores, of the same description as those found in the earliest openings of the Comstock. We have authentic reports of but two of these, though there are many others perhaps equally deserving of notice. The "Mount Ophir" and "Solomon's Ophir" are two locations apparently on the same vein. These ledges crop out to a width of 20 feet, and although requested not to give the figures, we may state that the ore assays immensely rich. The hills would appear to be full of minerals on every hand, and almost daily there arrive reports of new and very valuable discoveries. There are now about 150 men in the mines and more panning, in daily.

For the benefit of the outside public we will give the locality of these mines: They are 40 miles southeast of the foot of Owen's lake; seven miles east of the Independence and Panamint stage road, and about eight miles west of the head of Darwin cañon. They are easily accessible by wagon, and Dodge's passenger stage run within ten miles of the new town which is forming at the new mines, the proposed name of which is "Darwin." The essentials, water and wood, are found in far greater abundance than ever at Cerro Gordo. In conclusion we can only repeat to our citizens the advice proffered us by all of our informants. "If you doubt our statements go and see for yourselves and be convinced."

REMOVING HAIR FROM FIBRES.—A canny Scotchman has discovered that if a hide is immersed for four or five days in a mixture of vegetable or animal charcoal and water, of the consistency of a thin paste, the hair is entirely removed and the leather made from a hide thus treated is of superior quality.

STOVE LUSTER when mixed with turpentine and applied in the usual manner, is blacker, more glossy, and more durable than when mixed with any other liquid. The turpentine prevents rust, and when put on an old rust stove, will make it look as well as new.

MECHANICAL PROGRESS.

Cork as a Non-Conductor of Heat.

A company has been organized in Paris for the purpose of thoroughly testing the well known remarkable non-conducting property of cork. It appears that a number of steam pipes at several important establishments had been covered with this substance; but the test of continued application was wanting. More recently, however, it has been stated that, after standing 18 months, the cork covering has remained intact, and is as perfect a non-conductor as on the day it was laid. Although the durability of this substance had been proved before by the buoys, which are partly immersed and partly exposed to the weather; its being able to stand such high temperature as those of surfaces heated by steam at from seven to eight atmospheres had not hitherto been shown.

Now, felt, which is a good non-conductor of heat when first laid, deteriorates very rapidly; although retaining its original appearance, it ceases to be effective after a few weeks, and ultimately tumbles into dust.

A fear of the same result occurring in the case of cork would, no doubt, be entertained by those who are unacquainted with its nature, but not by those who know the composition of this remarkable wood-like substance. To set all misgivings at rest, however, nothing is so satisfactory as actual experience, and there is no doubt that cork is now firmly established as the non-conductor par excellence. Its lightness, the readiness with which it yields so as to surround the cylinders or pipes it may be destined to encase, the facility with which it is put in its place, taken down and put up again in the case of an inspection or repairs to a boiler or steam-pipe, and above all, its non-conducting power, effecting so great a saving of fuel, assure for it the highest place in the eyes of all manufacturers who regard their own interests.

The engineers of the French navy have made experiments on cork employed as a non-conductor, and have reported thereon to the Admiralty (French), which body has requested the manager of the company to appoint, at the five military ports, agents charged with attending to any orders which may be given. This *cachet* given by men so reserved as the French naval engineers at once places cork in the first rank as a non-conducting substance.

FREEING CAST IRON FROM PHOSPHORUS.—The new German process of freeing cast iron of phosphorus is represented as yielding superior bar iron from phosphureted cast iron, at practically no increase of cost. The method is very simple. Chloride of calcium and common salt, fused together in about equal proportions, are intimately mixed with the molten iron in the puddling furnace, either by adding gradually, in two-pound water tight paper packages, or placing the whole quantity required upon the bed of the puddling furnace at first, and, in either case, very thoroughly working it with iron. The puddling process is generally so much shortened that the consequent diminution of the waste iron almost affects the cost of the material added. The quantity of the mixed chlorides required is about three times that of the phosphorus present in the cast iron. The presence of other chlorides, as of manganese, iron and magnesium, interferes with the process, and renders a large excess of chloride of calcium necessary.

METALLIC PENS.—It was a fortunate thought which led some genius to substitute metallic pens for those obtained from the gray goose quill, for if to-day we had to depend upon these sagacious birds for our supply of writing materials, quill pens would be at a premium. So rapid has been the increase of knowledge, and so greatly has cheap postage promoted the desire and the power to write, that all the quills in the world would not furnish one-tenth of the necessary supply of pens. If, therefore, it had not been for the invention of gold and steel pens, our schools, our counting rooms, and our editors would have had hard times, during the time that has elapsed since quill pens were displaced by metallic ones, the form and material of these useful substitutes has been greatly varied, but notwithstanding the many forms which have been introduced, there is still great room for improvement, as every writer knows.

THICK AND THIN SAWS.—It is said that the manufacture of mortar, beton, and concrete, from the waste lime of gas purifiers—a discovery or invention announced only a short time ago—has already commenced on an extensive scale in England. The method of thus utilizing what has hitherto been considered an almost worthless refuse, consists, in this case, of simply grinding it up in an ordinary mortar mill, or mixing it as common lime with sand, ashes and similar material. The addition of Portland cement to the mixture is found to render the product—brick, slabs, etc.—much harder.

STEEL RAILS appear to be everywhere excluding those of iron. All of the contracts lately given out by the Belgian Government for the State line are steel. It is stated that steel rails are about as cheap now as iron rails were two or three years ago.

Belting and Gearing.

As regards the transmission of power, the Americans, says a French writer, aim at achieving two important things which are correlative—the lightest possible weight and the highest possible speed. Hence the universal substitution of belting for gearing, and the general adoption of light shafting and small pulleys, which are conspicuous features of their system of transmitting power. The first mover is usually a gear, but after that all transmission is obtained by belting. The belting is a little study in itself, but it will suffice to say here that belts of the latest improved pattern run for wonderful lengths of time without picking. The ease and durability of the system, would, I think, astonish the advocates of gearing. The light shafting and small pulleys in general use are said to save twenty-five per cent. of the power. The shafting is run twice as fast, and hence the pulleys can be smaller, yet the fly wheel of a powerful engine may be large. For instance, I have seen one twenty-seven feet in diameter going, as I was informed, a mile a minute. The pulleys are cast, but it is expected that wrought pulleys much lighter will soon come into general use. Hollow shafting is finding favor. If shafting and pulleys could be advantageously constructed of steel, the saving of power would probably be greatly increased. Engines and their equipments, and belting, shafting, and pulleys, are all made in the United States.

AIR PRESSURE IN WIND INSTRUMENTS.—Dr. W. H. Stone in a paper before the Physical Society, of London, describes some experiments on the wind pressure in the human lungs during the performance on wind instruments. About 6 feet of water or 13 pounds pressure per square inch was the ordinary maximum when a small tube was inserted between the lips. When the lips were supported by a capped mouth piece, as in brass instruments, a much greater pressure could be sustained, and lip muscles invariably gave way long before the expiratory power of the thoracic muscles was exhausted. The following pressures were sufficient to produce an orchestral tone: The oboe requires an air pressure of from 5 to 10 ounces per square inch, the clarinet, 8 to 14 ounces; horn, 2½ to 5 ounces; cornet, 5 to 18 ounces; euphonium, 1½ to 23 ounces; bombardone, 1½ to 20 ounces. It will be noticed that the clarinet, in this, as in some other respects, differs from its kindred instruments, and also that some of the pressures are small, not exceeding or indeed attaining the pressure of a fit of coughing. They are, therefore, very unlikely to injure the lungs, or to produce the emphysema erroneously attributed to them.

SPRINGS AS MOTORS.—The method of propelling cars, omnibuses and velocipedes by coiled springs is being tried in England, and with good prospects of success. The motor used is an arrangement of powerful springs encased in cylinders like watch springs on a very large scale. A car worked by these springs is shortly to be tried on the tramway at Greenwich. The services of French machinists have also been called into requisition, and steel bands capable of being coiled and of exerting great pressure have been made in lengths of one hundred yards each. In Sheffield some of the steel manufacturers have turned out springs fifty and sixty feet long, and said to be capable of a pressure of eight hundred pounds. To wind up these springs of course requires more power than could be obtained by hand, and the English experimenter proposes to have them wound at certain intervals by means of stationary engines. The result of the experiments will be looked for with much interest. Some of the English patents have a combination of spiral or helical springs.

PULLING UP FOREST TREES BY STEAM.—Some interesting experiments in the clearing of wooded lands took place lately in Scotland. The experiments were carried out under the auspices of the Canadian Land Reclamation Company and were intended to demonstrate the ease with which the forests of Canada could be cleared by means of this process. A traction engine of twelve horse power is stationed some distance off from the wood, and a wire chain is fastened to the tree. Steam is then put on, and the tree is pulled out by the roots. An objection to the adoption of the process was that it would injure the wood by splitting the tree; but the experiments showed that, with proper precautions, there was no fear of such a result. In five hours upward of 300 trees, in a plantation nearly 100 years old; were pulled out. Of that number not above half a dozen were broken, and in these cases the result was wholly due to the inexperience of the men engaged in the work, who placed the chain too high up on the tree.

COMPUTING THE SPEED OF GEARING AND PULLEYS.—The following simple rule for calculating the speed or gearing of pulleys is, doubtless, in familiar use by many mechanics. We give it, however, for the convenience of those of our readers who may not happen to be acquainted with it, and who have found the need in practice of a uniform rule, applying to all cases. To find the speed of a driven wheel, when the number of teeth of both wheels and the number of revolutions of the driving wheel are given: Multiply the number of teeth of the driving wheel by the number of its revolutions; divide the product by the number of teeth of the driven wheel, and the quotient will be the number of revolutions of the driven wheel.

SCIENTIFIC PROGRESS.

The Transit and Its Probable Results.

The full result of the patient watchings of the various parties deputed to observe the transit of Venus, will not be made known to the world for several months, perhaps not in a year from now; and they will probably be affected with a larger possible error than is generally anticipated. It will be some weeks before the telescopic measures taken at all the stations can be known, even if transmitted by telegraph, because many of those stations are far removed from any ocean cable at present in existence. At many of the stations the chief dependence will be on photographic views, and the negatives cannot be transmitted by means of the lightning flash; they can only be carried by the slower agency of steam to the observatories where they can be submitted to measurement with the micrometer. Then all the results obtained at separate stations must be compared, and many laborious calculations be made before the value of the solar parallax can be known.

Mr. E. Colvert, in some remarks at a late meeting of the Chicago Academy of Sciences said: "I have called your attention, at former meetings to the difficulties which will be encountered in the attempt to reconcile these observations; difficulties arising from, 1, the irregular shape of the earth, which is not a true oblate spheroid; 2, the irregular contour of the sun, its surface being in a state of perpetual commotion; and, 3, the errors of observation, which may be regarded as an external kind of 'personal equation.' Summing the probable average of these three factors of error, I conclude that the astronomical world will be fortunate if it is able to reconcile all the observations so as to make it certain that the accepted average is not more than 100,000 miles in error, or one part in 900 of the whole distance.

There is no reason to doubt that we already know the distance of the sun to within 300,000 miles. I speak not now of my own calculations of the quantity, but of the extremes claimed by others. If we assume 91,700,000 miles as the average, this estimate will not be more than 200,000 miles, from the 92,000,000 miles of Newcomb, or the 91,480,000 of the English computers. This is one part in 300 of the whole distance. Hence the probability is that observations of the transit of Venus in 1874, on which more than \$1,000,000 have been expended, and involving the equivalent of not less than 200 years of labor on the part of one man, will only reduce the uncertainty to about one-third of its present magnitude. But this will be no mean achievement. It is not saying too much to claim that this result will be worth at least ten times the money and labor expended in obtaining it."

PEAT CHARCOAL AS A DEODORIZER.—The extraordinary deodorizing power possessed by that variety of charcoal known as bone-black is generally attributed to the earthly matter with which it is mixed. It was therefore to be expected that peat charcoal should be specially valuable in this direction, and in some parts of England and Scotland it is now extensively used for mixing with the excreta of households on account of its value as a deodorizer. Peat charcoal is one of the most porous of all forms of impure carbon, and its powers of absorption when dry are very great. Thus, in some experiments tried in the town of Leamington, England, recently, it was found that two or three ounces of newly-made peat charcoal were sufficient to deodorize six gallons of ordinary sewage. The actual proportions employed, according to the report, were about one part of charcoal to 150 of sewage by weight; and in a few minutes after the charcoal was mixed with the rich aluminoid sewage, a peculiar sweet smell was noticed, but in less than a quarter of an hour all smell had disappeared, and the constant addition of fecal matter did not permanently restore the odor. A closet arranged for the purpose was devoted to the use of some forty laborers, but even during the hottest weather, on no occasion, was any offensive effluvia noticeable, although the amount of peat charcoal daily made use of did not equal the proportion already stated.

THE TELEMETER IN SURVEYING.—Captain W. H. Dall, in some remarks recently made before the Civil Engineer's Club, of New York, said that he had used the telemeter for four years on the coast and interior of Alaska. He had even more simple than Mr. French's, and he found that he could depend on his surveys being almost accurate, and in some cases much more so than if measured with the chain or tape. On rocky shores, the telemeter was invaluable, and in a few months he had, with the assistance of a common sailor, as rodmann, made surveys that by the ordinary methods would require fully five years to complete. He discovered after a time that for correct results an accurate focus was necessary, and to every observation the following correction or error in measurement was to be added, viz.: to the distance of the eye-piece from the object glass add the distance of the object glass from the diaphragm, which in the case of his instrument was exactly one foot. This subject of surveying with the telemeter is a very important one, and worthy of careful investigation.

The Development of Natural History and Science.

Mr. W. W. Calkins, recently before the Chicago Academy of Sciences, read a very interesting paper on "The Development of Natural History as a Science," of which the following digest is given in the *Engineer and Architect*:

The great lamented Agassiz said, "I have devoted my whole life to the study of nature, and yet a single sentence may express all that I have done." This confession reveals to us a degree of simplicity and grandeur not often witnessed. It suggests that the grace of modesty might be cultivated by most people with great propriety. Since man was first created he has been engaged in studying the world of animate and inanimate objects around him. As the first rude efforts seem to us like childish displays, so, when the present era shall become antiquity, our attainments in knowledge will no doubt appear small indeed in comparison with the advances that shall mark future ages.

Aristotle was the first prominent naturalist, and the founder of the science. As evidence of this, we have his "History of Animals." In Aristotle's time, 2,000 years ago, text-books of natural history were in common use, and the study was pursued with vigor. We are still without elementary works of this kind adapted to the young beginners. We are, however, working up to the point [when the study of natural history in the school will be indispensable and popular. After 1800, Linnæus resumed the work where Aristotle had left it. Pliny added but a little to what had been done by Aristotle. The Middle Ages, with an intellectual pall dark as night, followed the enlightened period of Roman and Grecian history, and gave us nothing. The sixteenth century witnessed a temporary revival in this and other branches of learning. The naturalists were mainly occupied in studying local species, and in disputing over ancient authors. The seventeenth century witnessed remarkable advances in general knowledge, but men had not yet done wondering over the successful revolt of the Netherlands, or the brilliant military career of Gustavus Adolphus, Wallenstein, and Tully.

It was reserved for Linnæus, in the last century, to break the spell that had for so many ages been hung over the pursuit of the natural sciences, and strike the key-note that aroused the scholars of Europe from their lethargy. Aristotle had given us genera and species; he divided the animal kingdom into *Enaima* and *Anaima*, or blooded and bloodless animals. Linnæus, beginning where Aristotle left off, formed, in addition, classes and orders. He divided the animal into six classes—mammalia, birds, reptiles, fishes, insects and worms. The classification at once aroused the attention and provoked the criticism of other naturalists. The defects were pointed out, and the important principle of classification founded upon the internal structure, and noting animals upon common structural characters, was established. The magnitude of the work of classification will be appreciated when we consider that the species now number 230,000. The confusion that existed before Linnæus' time on account of the different names and languages employed by naturalists was counteracted, and in fact done away with by the use of one language by him—the Latin.

Linnæus' classification, however, did not meet with entire success. Its effects did not escape criticism. All, with the exception of the great Cuvier, failed to strike the grand principles of classification. When he announced his theory dividing the whole animal kingdom into four classes—Vertebrates, Mollusks, Articulates and Radiates—the scientific world stood amazed, as though a revelation had been made from Heaven. The founder of comparative anatomy was not one who skimmed over the surface of things. Cuvier went deeper; he examined the internal organization and revelations of animals. He tells us the comparison was the secret of his success. The result embodied the four plans of creation already mentioned. The views of Cuvier, which have withstood criticism for nearly three-quarters of a century, lead to three conclusions: First, that Cuvier's four classes embrace all known animals. Second, that there is thought and harmonious law as the basis of all, the whole directed by one will—the Creator. Third, that the numerous subdivisions of the four great groups mentioned, such as classes, orders, families, genera, species and other subdivisions of these subdivisions, should be formed in accordance with characters expressed in nature to be of value. Otherwise they are artificial distinctions tending to lead us away from what we seek, and that which is the basis of all science—the truth.

Another great discovery hardly less important than those mentioned was that of Von Baer in embryology—or the fact that all animals originate from eggs, and though all alike at first, grow to maturity on four different plans. Embryology is yet in its infancy. Agassiz made some of his greatest discoveries in this science, and it furnishes one of the most attractive and promising fields open to the explorer. The progress of natural history for 50 years has been rapid. The latter part of the last and the beginning of the present century were particularly marked by great discoveries. The present century has produced hosts of distinguished naturalists who have labored successfully in their particular departments, but Agassiz, before his death, probably ranked first among living contemporaries.

Mr. Calkins closed by saying that the study of natural history should be popularized.

convey water to the Red Hill claim. When inaugurated this will be one of the most notable gravel mining enterprises in the county, and we believe it will prove among the most remunerative. Work is being pressed forward as rapidly as possible with a view to having everything in readiness for active operation shortly after the holidays.

WEST POINT DISTRICT.—Mina Rica continues to hold solid promises.—The former Thores mill was bought by parties, last week, who are now repairing mill and ditches.—Mr. Gilbert, "the last of the Modoca," bought out the Indians. Mr. Gilbert is now engaged in putting up a whim on the mine.—Loose Star is turning out fine ore again.—A working shaft has been commenced on the Josephine. At the depth of 12 feet the vein contains milling ore 4 feet thick.—A fine head of water has been tapped in the Good Faith tunnel.

CONTRA COSTA COUNTY.

MR. DIABLO QUICKSILVER.—*Contra Costa Gazette*, Dec. 26th: It is said that the new Quicksilver Mining company organized to work the ground of the old Welch company, near Clayton, have an ample working capital, and they are now putting up furnaces calculated to smelt 12 tons cinnabar rock a day. From the report of reliable parties who have been on the ground recently, we learn that the company have a large amount of rock awaiting the completion of the furnaces, all of which contains quicksilver, and some of it very rich. It is claimed that the rock now ready for smelting, although composed of croppings, or taken from near the surface, holds an average of from 30 to 50 per cent. of quicksilver, some of it going as high as 80 per cent. We are inclined to doubt if so good a return will be realized from the smelting, but there is still reason to believe, from the reports of disinterested persons who have inspected the rock already gathered, and that which has been uncovered—though no regular working has yet been opened, as we understand that the company have a valuable quicksilver claim which can be very profitably worked.

INYO COUNTY.

COSO DISTRICT.—*Inyo Independent*, Dec. 19th: Geologically, the formation is just right to give assurance of deep mines with immense chimneys of very high grade ores. Some of the mines, with croppings perhaps 20 feet wide and assaying over \$250 to the ton, are found near the crest of the hill or mountain, lying between a hanging wall of limestone and upon a foot wall of porphyry, the latter being the country rock to the eastward, and the other to the west. These mines all run nearly north and south, as does the mountain upon which they are situated. The recorder's book shows seventy-seven locations, all of ledges, except a few water rights. Of this number there are about thirteen, either one of which is considered of more promise than the famous Union of Cerro Gordo at the same stage of development. Taking the mines in the aggregate, there is abundant evidence that the bullion productions of New Coso can easily be made to more than double that of Cerro Gordo at any period up to the present. The ores, likewise, assay much higher, and are fully as easy of extraction, while the locality and the several mines are much easier of access.

MARIPOSA COUNTY.

FIRST SHIPMENT TO THE NEW MINING CAMP.—*Mariposa Gazette*, Dec. 26: The first shipment of supplies for "Reynold's Cove" passed through Mariposa on the "Flying Dutchman" prairie schooner last Tuesday, being 5000 pounds of freight. It consists of provisions, mining tools, a general assortment of supplies necessary for the commencement and prosecution of mining and other projected enterprises at the new locality.

REYNOLD'S COVE.—This place is situated on the main or middle fork of the Merced river, across the divide and opposite Hite's Cove, named from the discoverer of the celebrated Hite mine. From the statements of Mr. Angeline Reynolds, which are confirmed by the official map of County Surveyor Thomas, it appears that all the quartz veins cropping out at Hite's Cove are pitching at an angle of 35 to 60 degrees toward the main river—it being, in an air line, about a mile and a half from river to river; consequently, a tunnel run in from the main fork, commencing at a point about 2,000 feet from the river, as contemplated by the Reynold's company, would cut several veins of rich ore within a distance of 1,500 feet. At the adit or mouth of the proposed tunnel is an outcrop, of about 60 feet in length, of a vein showing a thickness of two feet, upon which the company propose running and extracting ore forthwith. In connection with the mining location the company has secured a water right and mill privilege, which, in point of convenience and advantages, cannot be excelled in any of the mining districts of California. Mr. P. C. Learned, the managing agent of the company, has been purchasing a complete outfit of supplies necessary for going on with the contemplated work, which will probably be commenced on or about the first day of January. With the favorable adjuncts of an abundance of wood and timber and an excellent water power, together with an excellent outlook for extracting paying ore, the prospect is rather encouraging.

MENDOCINO COUNTY.

THE AMARRILLO MINE.—*Napa Reporter*, Dec. 26: John L. Cook, the locator of the Oakland mine, writes us from Mendocino county, whether he has been called to superintend the opening of the Amarrillo mine in that county, and from which he has had the glory of ship-

ping the first flask of quicksilver ever sent from that county. The mine is owned by Mr. Wise, a capitalist of Cloverdale, and bids fair to turn out a very remunerative one to its proprietor, especially, we think, as he is so fortunate in a superintendent. Three tunnels are already in, and the developments of rich cinnabar are large in each. They have one retort up, and will shortly erect more. This new district is showing some fine ledges, and many claims are being located, with every prospect of proving as rich as those in Lake, Sonoma or Napa county. The Amarrillo mine is situated about twelve miles north of Cloverdale, on the Ukiah road.

NAPA COUNTY.

MINING ITEMS.—*St. Helena Star*, Dec. 24: We have the following from a friend, who has just returned from a visit to Pope valley and its mines of quicksilver. The Phoenix has dropped into a No. 1 deposit of ore, of a character before unknown in the mine. It is rich cinnabar, interspersed with native quicksilver to a large amount. On the part of the Etopa mine, they are for the present at rest as regards the furnace, but are getting ready to work their rich deposits in the early spring, both in the Valley mine location and also in the Silver Bow, where they have a large body of extra ore, as good as any that has ever been worked in the course of mining done in that valley. Geo. Porter and Harry Vivian have a splendid prospect on the Out hills at the head of James creek, and from specimens in our possession we judge they are all right. They have now two sixty foot tunnels and good bodies of ore in both.

CALISTOGA MINES.—Mr. Stuart, of the Knight's Valley ranch, is going to work on a new plan to save the disintegrated cinnabar at the Yellow Jacket mine. It is nothing more nor less than hydraulic mining just as they work placer diggings for fine gold. Everything will be ready for a trial of the machine in a few days, and then down comes the mountains in the vicinity of Stuart's ranch. This is, as we understand it, an entirely new thing in quicksilver mining, if successful, will be the inaugural of a new era in that branch. Calistoga has reason to be proud of her success as a mining town. During the month of November there has been shipped from this place over 40,000 pounds of quicksilver, and, as yet, the business has only begun.

NEVADA COUNTY.

NEW YORK HILL.—*Foothill Tidings*, Dec. 25: Last Friday night after our issue had gone to press, a rich strike was made in the New York Hill mine. Pay rock has been coming out all along for three or four hundred feet in the lower tunnel. This strike was made in a cross-cut from this tunnel and at a point beneath, on the incline, a body of good ore in the upper tunnel. Here are several hundred feet of good licks that may be considered "in sight," and as the richest of the rock now found was at the bottom, there's something big to go for below. On Saturday we examined a lot of specimens, weighing a hundred pounds or over, taken from the first car load of the strike, and placed on exhibition at the banking house of A. Delano. It was nearly all so filled with gold as to be more valuable for jewelry than for milling. The lot was estimated to be worth from \$1,500 to \$2,000. Much fine ore has been taken out since, and the mine is now considered past all doubt as to its future. The benefit to Grass Valley of this assurance of a good mine in New York Hill, may be better appreciated after reading over the Idaho reports in this number of *Tidings*.

Too cold for quicksilver to work well in amalgamating; the gold—in the news from above and throughout the county. As we intimated last week, an early supply of water is seldom advantageous, as, for the reasons above given, miners can't work much before February.

The Omaha mine is said to be turning out good milling rock from a fair sized ledge, and the stockholders feel in good spirits.

NEW QUARTZ MILL.—*Nevada Transcript*, Dec. 25: Hon. Jack Pelham and Mr. McDonald, of Grass Valley, some time since bought the Gaston Ridge mine, located midway between Washington and Eureka, in this county. The ledge was worked several years ago, and although the rock was good, it failed to pay dividends, from the fact of the imperfect facilities for working the rock and saving the gold. The present company have, during the past two months, had a new ten-stamp mill erected, and will thoroughly test the mine. We are informed by Mr. T. Looney, who will take charge of the mill, that the ledge is large and the rock looks well. The mill is completed, but will not start until after New Years. There is a large number of ledges in the vicinity of this mine, and if it pays will be the means of starting up work on many of them.

PLUMAS COUNTY.

NEW PLUMING OPERATIONS.—*Plumas National*, Dec. 16: Mr. Charles Hambley informs us that a company has been organized to work Soda creek, above Soda bar, and work has already been commenced. They will start at the river, put in a four-foot flume, and clean the creek as they go. The company will put up a portable sawmill, which will be used for manufacturing flume lumber, blocks, etc., and also to furnish the general demand for lumber in that section. Soda creek is thought to be very rich in places, and the new company propose to "sweep it clean."

SAN LUIS OBISPO COUNTY.

CAMBRITA ITEMS.—*San Luis Tribune*, Dec. 19: The quicksilver interests still increases. Sev-

eral parties are here from the city in search of mines; among whom is our former townsman, George Mowatt. George is a lively lad, and evidently means business. Some parties are negotiating for the Gibson and Phillips. This mine has one of the finest prospects in this district. The company have, however, been very unfortunate in allowing third-rate men to dabble with its mine.

SIERRA COUNTY.

SLOC CANYON.—*Mountain Messenger*, Dec. 26: The owners of Sloc canyon quartz mine have engaged a force of men to put their tunnels in order. There is undoubtedly a fine body of ore in this mine, if it were only properly developed. A tunnel not to exceed 400 feet in length, would top the ledge several hundred feet in depth.

ORO.—A considerable amount of stock in the Oro Gold Mining company has already been sold to parties in this place. There is no doubt but that enough will be disposed of to enable the building of a suitable mill. The company has a large amount of ore in sight, ready to be taken out when they have any way for reducing it.

CLAIM SOLD.—Col. Baker, of Gardiner's Point, has sold his mining claim, including the Pioneer ground and several other claims, making the purchasers sure of having one of the best hydraulic mines in the State.

CHINA MINING.—The China companies, three in number, are doing well.

NEW PROSPECT.—Henry Von Millen has struck a good prospect on Lafayette ranch.

Nevada.

WASHOE DISTRICT.

PHIL SHERIDAN.—*Gold Hill News*, Dec. 24: West drift in to-day 155 feet from the shaft. The face of the drift has been driving into blue clay and quartz the last few days, with a constant increase of the quartz, and yesterday afternoon still more favorable material was met with. In the upper tunnel of this mine, 750 feet above the level of the present workings, a large strong vein of solid quartz or low grade ore was developed, and this lower drift is probably about cutting the same vein.

CONSOLIDATED VIRGINIA.—Daily yield, 425 tons. The ore breasts of the 1300 and 1400-foot levels, especially the latter, are looking splendidly. The winze below the 1550-foot level is sunk to a depth of 72 feet. This winze is now passing into the western formation, leaving the ore body to the eastward. The north drift on the 1550-foot level is advancing toward the northern boundary line through ore of the highest grade. On the 1500-foot level, cross-cut No. 1 has already penetrated the ore body a distance of 65 feet. The quality of the ore exposed in this drift is very fine for the entire length of the opening. Cross-cut No. 2 on this level is extended 265 feet through ore of steadily increasing value, and has not yet reached the east wall. Throughout the mine the ore stopes are yielding well and the quality of the ore is rich.

HALE & NORCROSS.—The prospecting operations in this mine are confined to the lowest levels—the 2000 and 2100-foot levels. On the 2000-foot level the cross-outs have been carried almost entirely across the ore vein without exposing good ore in sufficient quantity to justify its extraction. On the 2100-foot level the north drift is advancing in the ore vein, and is now approaching a locality in which ore is supposed to exist.

JULIA.—The shaft is now being sunk at the rate of 4 feet per day. It is now 1113 feet deep and the bottom in excellent working ground requiring no blasting, the material being quartz, porphyry, and clay.

FLORIDA.—Sinking at the bottom of the shaft is resumed and making good progress, the ground working well and water not interfering. The machinery works excellently, but a heavier engine, with the requisite boiler, is ordered for deeper working.

SAVAOR.—Sinking the main incline makes the usual good progress, and some little improvement is noticeable in the prospecting developments at the 2000-foot level.

GOULD & CURRY.—On the 1700-foot level the north drift is advancing to unite with the winze in order to improve the ventilation, and thereby allow of the thorough exploration of that level. The volume of water flowing from the east drift on the 1500 foot level does not increase and is easily removed.

JUSTICE.—The main drift is giving a fine showing of ore at present, with continued improvement. Excellent assays are obtained from the face, and very high ones from the west side of the drift.

ORIGINAL GOLD HILL.—The northwest drift at the 340-foot level has assumed a north direction, and shows low grade ore and porphyry in its face. A cross-cut east, from it, is now in six feet, and shows pretty fair ore in its face, which improves as further advance is made.

CROWN POINT.—Daily yield, 500 tons, from the old ore-producing levels. Nothing new in the way of ore developments in those sections; the breasts and stopes hold out excellently, and bid fair to do so for a long time to come. Prospecting is resumed at the 1500-foot level, east, in the south and middle cross-cuts, running farther east in order to see if pay ore cannot be found in that direction.

CHOLLAR-PODSOL.—Daily yield, about 50 tons per day. The old ore sections show improvement in quality, with plenty of ore in sight as yet. Average car samples assay \$30 per ton.

EAST BELCHER.—The large new three-compartment working shaft is being sunk at a good rate of progress.

YELLOW JACKET.—The drifts both north and

east at the 1740-foot level are making good progress, and the north winze below the 1740-foot level is considerably encumbered with water.

SUTRO TUNNEL.—Progressing at a very lively rate—about 15 feet per day. Rock works easily and water does not interfere. Those Burleigh drills do splendid execution. Total length of tunnel from mouth in header, 8013 feet to-day.

WOONVILLE.—The mill is kept steadily running on ore from the 200 and 300-foot levels, and new ground is being opened below the 300-foot level.

UTAH.—Grading for the new pumping machinery is progressing favorably. Sinking the shaft will not be resumed until the new engines shall have been placed in position.

BELCHER.—Daily yield 450 tons of ore. The drift east from the 1500-foot station of the main incline, to open that level, is also going ahead well. Sinking the main incline goes ahead as usual, and it is to-day 50 feet below the 1500-foot level. The new air shaft is down 220 feet from the surface, and the npraise portion of it, from the 850-foot level, is up 120 feet.

OPHIR.—Daily yield, 240 tons, from the ore breasts and stopes of adit between 1300 and 1645-foot levels, keeping 4 mills steadily running. The cross-cut from the winze below the 1645-foot level, near the California line, continues in splendid ore; in fact there is plenty of rich ore in sight in the Ophir, and all the cross-out and winze explorations simply go to show that the great bonanza extends downward and northward. The quality of the ore extracted during the past week was better than heretofore, giving much higher assays; therefore, the milling returns will be much better.

IMPERIAL EMPIRE.—The cross-cut at the 2000-foot level is apparently near the ledge. Occasional flows of hot water are met with, and the drift is kept well timbered in anticipation of any heavy body of water that might be tapped in cutting through the wall of the ledge.

ROCK ISLAND.—The indications thus far met with in this mine are very flattering, and show very plainly that depth only is needed to find a good body of pay ore.

SIERRA NEVADA.—Daily yield, 60 tons, principally from the old upper workings, keeping the company's mill running.

OVERMAN.—The 1100-foot station for a new level and drift to the ledge is now being opened. As soon as the 1100-foot station is well advanced, sinking at the bottom of the shaft will be resumed.

LEO.—The face of the north drift shows some stringers of very good ore, indicating that a large body of ore may be soon developed.

BALTIMORE.—At the 750-foot level the seams of quartz in the face of the drift are widening and give high assays.

SILVER HILL.—The face of the south drift at the third level is in fine looking quartz carrying considerable metal. The face of the south drift on the second level is in low grade red quartz ore the full width of the drift and still widening.

SUCCESS.—The pump has been doing effective service, and the water being lowered sufficiently, work is resumed in the drift.

LADY BRYAN.—New shaft down to-day 373 feet. The new pump is in place, and assists progress very materially. The drifts for the ledge are going ahead well.

CALIFORNIA.—A shaft has been started in connection with the adjoining mine, the Consolidated Virginia, at a point 1,040 feet east of the shaft of that mine. In the California, cross-drifts are now advancing towards the ore body on the 1400-foot level, at a point 200 feet north of the south line of the mine, and on the 1500-foot level, 100 and 200 feet northerly from that boundary. It is expected that the ore body will be reached by these transverse drifts early in January. The richest ore developments in the Consolidated Virginia are very close to the southern boundary of this mine, and their extent is yet undetermined.

MINT.—Sinking the shaft for another level is making good progress.

NEVADA.—The good yield of ore from the old chimney of the upper workings continues, and the face of the lower tunnel is in low grade ore.

MEXICAN.—The drift from the 1465-foot level of the Ophir to prospect this mine is going ahead, with nothing interesting to report as yet.

A New ledge with a very promising appearance has been found on the south-western side of the ridge back of Pioche. The owners are, Murphy, Jones & Co.

The necessary machinery for working the Amador quicksilver mine has been purchased, and will soon be put in active operation.

It is estimated that the shipments of bullion from Utah Territory the past year amounted to \$7,000,000.

A Bed of coal has been discovered on Chambers' creek, near Stellacom, Washington Territory.

An inexhaustible supply of potter's clay has been discovered at Whatcom, Washington Territory.

Advices from Banner mining district, San Diego county, say all the mills are running, and times are lively.

The South Mountain Consolidated Mining company have contracted for 3,000,000 bushels of charcoal.

The railroad company is negotiating for Moore & Parker's coal mine, near Carlin.

Development of the Iron Interest.

A project for the development of the iron interests of this State says the *Calaveras Citizen* has at last assumed definite shape, and as soon as the necessary arrangements can be perfected active operations will be commenced. A company of Eastern capitalists have purchased an iron mine in Shasta county, and their agent is now making preparations for putting up the necessary works for manufacturing purposes. The company propose to erect their works—rolling mills, etc.—in Sacramento, provided the city will donate a site. A meeting of the citizens of that place was held a few evenings since, to consider the matter, at which money enough was subscribed to ensure the purchase and donation of the location desired by the company. It is intended to manufacture steel rail as well as all other different varieties of iron for which there is a demand on this coast.

The successful prosecution of this enterprise will result in incalculable benefit to the State. Besides giving employment to a great number of skilled hands and laborers, it will be but the beginning of the development of an industry that is certain to become one of the leading interests of the coast. But few people have a correct idea of the quantity of iron annually consumed in this State. It is estimated that \$5,000,000 will not more than cover the yearly expenditure for that article—every pound of which is now imported—\$1,500,000 being paid out for the single item of nails. This vast amount of money is taken out of the State to pay for that which can and ought to be produced at home, a mode of doing business that for years has told heavily against the prosperity of California. The inauguration of iron manufacturing here will stop importation, in at least one very important particular, and encourage the building up of a general system of manufactures that the State can never reach its full measure of prosperity without. We are not yet wholly acquainted with the purposes of the Eastern company. We do not understand whether they intend transporting the ore to Sacramento for reduction, or whether they will make pig at the mine and work the metal, simply, in the city. The cost of transportation will undoubtedly have much to do with settling that question, which, however it may be determined, will in no way detract from the importance of the enterprise.

We regret that Calaveras was not selected as the initial point for iron making. This county possesses a number of advantages over Shasta for the prosecution of that business which the Eastern company must have overlooked in choosing their location. An analysis of the Shasta and Calaveras ores proves that the latter are the richer of the two, a fact that cannot be too strongly emphasized when it is considered that transportation is the chief item of expense connected with manufacture. There are unlimited quantities of hematite ores in this county that assay as high as sixty per cent. iron, while the best specimens from the Shasta field do not show above thirty-five per cent. This difference in the quality of the ore is an advantage in favor of Calaveras, that can be scarcely be over-estimated, and it is strange that so important a fact was lost sight of by those seeking the best place to engage in the manufacture of iron. Further than this, Calaveras is much more favorably located than Shasta for the successful production of iron, being nearer a market and closer to main thoroughfares of transportation. So far as the question of fuel is concerned no county in the State possesses advantages superior, if equal to Calaveras, and all other requisites for iron-making are to be had in abundance. While we are sorry that Calaveras is not to have the honor of making the first ton of iron produced in the State, we have all the faith in the world that the time is not far distant when the county's resources, in that respect, will be developed. The success of the Shasta enterprise will stimulate research, and the great advantages of this county cannot be much longer overlooked. Calaveras needs but the unfolding of its latent resources to place it in the front rank of prosperous counties, and we believe the development of the iron interest will be the first step taken in that direction.

BARTLETT CREEK.—The *Silver State* says of this district: At present there are one hundred or more prospectors in the district, nearly all of whom have interests in one or more mining locations. The hills abound in ledges, and new discoveries are made daily. A cut or trench 40 or 50 feet long at right angles with the course of the veins is certain to strike one. But few of them crop out on the surface, the veins generally being what are called by miners "blind ledges." Bartlett creek at all seasons of the year is capable of running six or eight ten-stamp mills, all of which can be built within a few hundred yards of each other, as the stream runs through a steep cañon and is exceedingly rapid. As a general thing the veins as far as developed are small but exceedingly rich. The town of Varyville recently laid out contains three saloons and one store. Mr. Merchant is of the opinion that the mines are permanent, and that Columbia district will be one of the liveliest in the country next spring. Eight or ten miles from Varyville is the newly located Saw Creek district.

The celebrated Jersey mine, in Jersey district, has been sold for \$31,000 to Sacramento smelting works. Jersey district is situated in Humboldt county, about forty miles southwest of Galeana.

Columbia District.

The following, from G. F. Harris, a practical assayer, relative to Columbia mining district, in this county, we find in the *Modoc Independent*, a new paper just started at Dofris' bridge, Modoc county, California: The 'Badger mine, owned by Messrs. Vary, Keating & Merchant, is fast developing into a valuable mine. The ledge has been tepped all along for a distance of 1,000 feet, and in each place exhibits a fine body of paying ore. Two shafts sunk on the ledge to a depth of about 60 feet only, strengthen the conclusion that the mine is one of immense wealth. An arastra belonging to the Badger has successfully worked 80 tons or more, yielding a return of about \$4,000, and the tailings which remain are of efficient value to pay for re-working. Mr. Vary has sold a one-third interest to a man named Bolinger, for \$7,500, and the last named gentleman has gone to San Francisco to procure a quartz mill, which he intends to put upon the ground at once, and his return was daily expected when I left (on the 15th instant). Mr. Johnson, from Silver City, as I was informed, was en route for the camp with his two-stamp mill, and has arrived ere this if he met with no mishap. Messrs. Geary & Mathews, of the Rosedale, No. 1, had made a good strike in that claim, and had shipped about one ton of ore to the Winnemucca mill as a test. Judging from several assays made of the rock by myself, I place its value at from \$40 to \$60 a ton. The Rosedale claim, No. 2, owned by Mr. Keating, Campbell, myself and others, is of very much the same character of ore as the claim described, and is beyond gainsay a true fissure. The vein has been uncovered at intervals of a few yards for several hundred feet, and shafts show it properly in its casing. The encasement of the vein on its eastern or hanging wall, is a soft micaceous granite which the gorge follows, while the western or foot-wall is a quartzose granite of a more stubborn nature. The gouge or vein ribbon that follows the hanging-wall, is a calyx patty or clay, which we are led to believe never exists except in true fissures.

The base metals, copper, galena and antimony, appear in small quantities, and the most remarkable feature of this ore consists in these metals always appearing separate and distinct from each other, and from the gold. The galena and antimony, however, seem to carry the greater part of the silver. Thus an expert can easily separate the free milling ore from the baser with his eye. There are several other claims which might be mentioned as of promising value, and in fact may prove the most valuable of all, but as the development of each has not gone far enough to admit of an opinion, I will in this connection only express a wish for their future prosperity.

New Oregon Mines.

An excitement is raging with regard to a recently discovered quartz ledge, situated in Josephine county, Oregon, at or near the junction of Galice creek with Rogue river. This place is a little to the west of Jacksonville, and distant therefrom about fifty or sixty miles. The Jacksonville *Times* has the annexed on the subject:

"The excitement consequent upon the discovery of the quartz mines at Galice creek seems to be on the increase. Several of our citizens have left for that section to see what prospect there is of 'making their pile.' Parties from other parts of the State are also arriving upon the scene, among whom are Judge J. H. Reed and W. H. West, of Portland. Judge Reed formerly owned some placer mines on the creek, but, we believe, sold them a short time ago. The ledge is of immense proportions, some saying it can be traced for twenty-five miles, while its width is estimated as high as two hundred feet, with a depth of 500 feet in sight. The assays of ore from this ledge, made by various assayers on this coast, speak favorably for its richness. We understand that it is the intention of Mr. Courtney, one of the persons interested, to ship lead for milling a few tons of this rock, so as to fully test its value and ascertain if the ore is refractory or not. This movement will be necessarily retarded some time, as, owing to the rough roads, it is impossible to do so now. Should these discoveries prove as rich and extensive as we have cause to believe, money will be more plentiful than ever before, for there is enough for all. Jackson and Josephine counties cannot be benefitted more by any enterprise than by the successful working of these mines.

PANCAKE MOUNTAIN COAL.—A large specimen of coal from Panake mountain was brought by G. D. Howell to this office to day. The specimen is of a good quality, and we should judge far superior to the Mt. Diablo article. It burns freely and leaves a clear, white ash. It is evidently a combination of anthracite and bituminous, and for the manufacture of coke is said to equal the best Pittsburgh candle coal. At the depth of 400 feet the vein is 34 inches in width, well defined and solid, and appearance indicate an extensive and valuable deposit. There are seventy-five tons already on the dump, and the pile is being increased at the rate of about four tons per day. Experiments in the manufacture of coke have been entirely successful, and arrangements are being made by the company for the manufacture of the article upon an extensive scale.—*Eureka Sentinel*.

City Mining.

The *Mountain Democrat* says: There are very few town lots in Placerville proper but have been mined out and filled in once, twice, thrice or oftener, but within the past week we have noticed quite a lively revival in this line. Chinese companies pay an agreed sum for the privilege of mining out a town lot, leaving the buildings thereon intact by underpinning and propping them up, and after the gold is all washed out the lots are filled up by turning in the water and depositing the sediment from other mines above. For these mining privileges in town lots, very respectable prices are sometimes paid. Companies are now at work in the lumber-yard lot of Jones & Co., lower Main street, in Limpinsel's lot, on Main street, above Bedford Avenue, and in the Burns' dwelling-house lot, on Main street, just above Limpinsel's. The privilege of mining the Jones lot sold for \$1,000; the same privilege on the Burns lot sold for \$350, and Limpinsel also obtained a good price, though he has not made it public. Negotiations are pending for a lot 107 by 167 feet at the lower end of Main street, \$2,000 being the present owner's bed-rock price. If the code and the law officers of the county would permit it, there are well posted old residents, principally business men, who would give a handsome sum for the privilege of mining out Main street from Jones' corner to the Central House, Coloma street, from the upper corner of our office to Main street, and Sacramento street from the corner of Main to a short distance above Dunn's blacksmith shop. This would include the width of the streets for a distance of about 300 yards. Responsible parties have offered \$10,000 for the privilege of mining out this ground, obligating themselves to leave the streets in an improved condition, with a large and substantial sewer the whole distance, which would much improve the adjacent property. From results obtained in digging cisterns and otherwise, those best qualified to judge are confident that not less than \$100,000 could be made in thus mining out the portions of streets above indicated.

Prospecting Northward.

Already are our prospectors pushing northward, as we a few days since predicted would be the case. Making the Ophir mine the center of the Comstock, there has as yet been but little real prospecting done to the northward. Southward we see lines of fine hoisting works extending a distance of two or three miles, while to the northward we have only the works of the Sierra Nevada and the Utah companies. These are the only companies north of the Ophir where steam hoisting works are in operation, and are the only companies that have shafts of any considerable depth. The grand rush of prospecting companies has always heretofore been to the southward. Now it seems that the north end of the lead is to be looked after. In taking a drive to the race-track, three miles north of town, yesterday, we observed men at work in several places. Even out beyond the toll house, where we turn from the Geiger grade to go down into the valley in which the race-course is situated, we saw men at work in long, open cuts, throwing dirt right and left, like so many gophers. They seemed bound to head off the big bonanza should it be found to be coming in that direction. Still, beyond these, were to be seen on the hill-sides signs of mining operations. Next spring we shall doubtless see work resumed and earnestly prosecuted in all the old shafts and tunnels, and some valuable discoveries may result. It is beginning to be apparent that just when we thought we knew all about the great mineral belt in which the Comstock lode is the principal feature, we knew next to nothing of the Comstock itself. Had we known three months ago what we now know, many of us might now be in possession of millions where we have not dollars. This being the case the work of sinking shafts and making explorations in the mineral belt should be encouraged. The surface looks the same to the northward, where men are now just beginning to dig, as it does over the Ophir, California and Consolidated Virginia claims. The ground that meets the eye as we walk over it looks equally common and valueless. In the silver-bearing belt valuable discoveries are liable to be made, even in excavating a cellar or digging a well.—*Enterprise*.

THE NEW MINE.—The new Mexican mine on the Comstock, though still a portion of the original Ophir ground, has no connection with the old mine of the same name, but is simply the north division of the Ophir. This heretofore comprised 1,275 feet, but it is now divided, giving the Mexican 600 feet, and the Ophir 675 feet. The Mexican has 168 shares to the foot, and Ophir 150, or 149 shares and a fraction to the foot. By this division, the holders of Ophir receive a stock dividend of one share of Mexican to each of their shares of Ophir. The Ophir has the cream of the thing, that is to say, it has all the ore thus far discovered and belonging to the recent rich developments; but this is expected to extend into, and perhaps beyond the Mexican. The name of the new stock as it appears on the quotations of the Board, has a familiar look to old residents, who remember the time when in describing the discovery of ore of the highest grade, it was only necessary to say "it is almost as rich as the Mexican."

Napa County Mines.

The *St. Helena Star* says: The year approaching to a close has been one of general prosperity to Napa county. The returns from the agricultural and new mining districts of the county have been of a much more satisfactory character than anticipated, which is well, because it is seldom that we get more of this world's goods than we expected. Crops of all varieties have been abundant, and prices, as a general thing, have ranged liberal and in some cases high, thereby acting as a blessing to the producer, and also standing off the backs of previous bad years, and encouraging him to make the coin "doat," conferring, as it were, to the community at large a general benefit. Indications for a continuance of our mining and agricultural prosperity, to say the least, are actually of that character, wherein one is apt to say "you flatter me." As yet there is no evidence to dispute the assertion; we have had copious rains, promising excellent pasturage; an important advantage to live-stock holders at this season of the year, while a large area of soil has been turned up for seeding, which, in many cases, has already been done. With the rains, common to this month, crops will get an earlier start, thus lessening the contingencies at the tail end of the season. The condition of things thus assured is an item of vast importance.

The mining industries of the county have, to no little degree, contributed to our general prosperity. By close figures we find that, since spring, there has been something like \$300,000 brought into the county in the shape of mining machinery, and that over \$2,000,000 of dollars has been paid to our mining population, much of which has found circulation in this county, in a general way benefitting everybody. Of course not directly, but like the air we breathe, we feel its life.

A knowledge of this state of facts inspires encouragement to all classes. The more plentiful supply of money has already the effect of producing lower rates of interest. One per cent. per month is now quite sufficient, where, last year at this period, one and a half ruled as easy.

The amount of building and improvements consummated and going on surpasses anything of the kind that has in one year been attempted, affording constant employment to mechanics and laborers at remunerative prices, which, in turn, has stimulated all branches of trade. Trade throughout the county was never on a more healthy basis. Merchants are laying in large stocks to meet the prospective demand of the holidays, and all this comes of the prosperity enjoyed during the year and the kind indications which foreshadow the next.

OF DOUBTFUL PRACTICABILITY.—The main feature of a new plan for raising sunken ships is closing hermetically the hatches and all openings in the upper parts, and then pumping down air through tubes inserted through the bottom. The air thus introduced rises toward the under side of the deck, and not being able to escape, presses the water down and out through the holes in the ship's bottom. The vessel by this means will be rendered buoyant and rise to the surface. It is obvious, however, that in order to insure success, it will be necessary to seal up the deck and upper part of the vessel so thoroughly that no air can escape. We do not believe that this can be done at moderate cost, and if it were done we feel certain that the straining and racking of the vessel would open the seams, let out the air and undo all that had been done.—*Indus. Monthly*.

BULL RUN AND CORNUCOPIA.—From Ben. Painter, a Nevada pioneer, who arrived here a few days ago from Bull Run, we learn the following: The Blue Jacket mill is rapidly approaching completion. The mine has been tapped by a tunnel several hundred feet lower than the old works, and at the point of intersection carries two feet of high-grade ore. At Cornucopia the new mill had steamed up for the first time, last Wednesday, though the mill will not commence crushing ore for eight or ten days yet. Painter came down for a load of provisions, and expects to start homeward tomorrow. He says the roads are in excellent condition.—*Silver State*.

FASTENING IRON IN STONE.—A writer strongly recommends the use of zinc instead of lead for fastening iron railings into stone. It is well known that iron cemented with lead is consumed by rust very rapidly and destroyed. The zinc, however, establishes a galvanic circuit with the iron, and being positive to the iron, constrains all the chemical action and becomes oxidized, while no rust forms upon the iron. With lead the opposite takes place. It makes also with iron a galvanic combination, but the iron being positive compared with the lead, it undergoes the chemical action, is oxidized, and protects the lead at its own expense.

MARKING TOOLS.—Much trouble can often be saved by marking tools with their owners' names, which can easily be done in the following manner: Coat over the tools with a thin layer of wax or hard tallow, by first warming the steel and rubbing on the wax warm until it flows, and let it cool. When hard, mark your name through the wax with a graver, and apply aquafortis (nitric acid); after a few moments, wash off the acid thoroughly, and wipe it off with a soft rag. The letters will be found etched into the steel.

GOOD HEALTH.

Washing Out the Stomach.

Dr. C. Ewald, of Berlin, describes a method of washing out the stomach, which, on account of its great simplicity seems likely to make the topical treatment of diseases of the stomach, especially in cases of poisoning, much more common: "A piece of ordinary India rubber tubing, such as is used for gas-lamps, about six feet long, is used. One end is rounded with scissors, and, if necessary, two holes are cut at a short distance from the end. This tube possesses quite sufficient rigidity to be pushed without difficulty into the stomach. To the outer end a funnel is fitted, into which can be poured either water or a solution of soda, etc., according to circumstances. If the contents of the stomach are to be removed the outer end of the tube must be sunk to the level of the pube, or even lower; then the patient must make a short but forcible contraction of the abdominal walls. By this means the tube is filled to its highest point with the contents of the stomach, and becomes a siphon; the liquid continuing to flow until there is no more, or till the tube is stopped.

This last seldom occurs, if the tube be of a moderate calibre. Should it, however, happen, or the abdominal pressure be insufficient to fill the tube in the first instance, or the patient be insensible, or any similar difficulty arise, it can, in general, be readily overcome by fitting a common syringe to the end of the tube, one stroke from the piston of which is generally sufficient to remove the obstacle.

THE HOURLY DEATH RATE.—Dr. Lawson, an English physician, has recently published some curious observations regarding the time of the day when the greatest and least number of deaths occur. He finds, from the study of the statistics of several hospitals, asylums, and other institutions, that deaths from chronic diseases are most numerous between the hours of eight and ten in the morning, and fewest between like hours in the evening. Acute deaths from continued fevers and pneumonia take place in the greatest ratio either in the early morning, when the powers of life are at their lowest, or in the afternoon, when acute disease is most active. The occurrence of these definite daily variations in the hourly death rate is shown, in the case of chronic diseases, to be dependent on recurring variations in the energies of organic life; and in the case of acute diseases, the cause is ascribed either to the existence of a well marked daily extreme of bodily depression, or a daily maximum of intensity of acute disease.

SIMPLE DYSPEPSIA REMEDIES.—Dyspepsia arises from a great variety of causes, and different persons are relieved by different remedies, according to the nature of the disease and condition of the stomach. We know of a lady who has derived great benefit from drinking a tumbler of sweet milk—the richer and fresher the better, whenever a burning sensation is experienced in the stomach. An elderly gentleman of our acquaintance, who was afflicted for many years with great distress after eating, has effected a cure by mixing a tablespoonful of wheat bran in half a tumbler of water, and drinking it half an hour after his meals. It is necessary to stir quickly and drink immediately, or the bran will adhere to the glass and become pasty. Coffee and tobacco are probably the worst substances persons troubled with dyspepsia are in the habit of using, and should be avoided. Regular eating of nourishing plain food, and the use of some simple remedies like the above, will effect in most cases quicker cures than medicine.—*Scientific American.*

NELATON'S TREATMENT OF BOILS.—A French medical journal says that Nelaton for more than 20 years prescribed the use of alcohol for the prevention of these smaller abscesses which are so common among young people and which so seriously impair the beauty of the face. It appears that this treatment is now extending. In speaking of boils and outward abscesses, and other inflammations of the epidermis and of the derma, he observes that as soon as the characteristic circular redness appears on any part of the body, whatever may be its size, with a point rising in the middle, making it a grayish white, a thimbleful of camphorated alcohol should be poured into a saucer; the palm of the hand should be wetted with it and this should be rubbed with gentle friction over the affected place. The fingers should be again steeped, and the friction continued as often as eight or ten times every half minute. The place should be well dried and before covering it up a little camphorated olive oil should be applied to prevent the evaporation of the fluid.

REN WALL PAPER DANGERS.—To the dangers due to the arsenic entering into the pigment used in staining green wall paper, must now be added others produced by coralline dye employed in the coloring of red hangings. It appears that the poisonous symptoms (extending to acute eruptions of the body, when under garments thus dyed are worn, and to eye diseases in papered rooms) are owing not directly to the coralline, since recent experiments have proved the substance to be harmless, but to an arsenical mordant used to fix it. This last acts as a poison, both topically upon the skin, through contact with garments, and also by its dust and vapors, disengaged from the stuffs which it colors.

Health and Marriage.

Mr. Francis Galton, of the Royal Institution (Eng.) in some late remarks before that body on the healthy nature of scientific work, made a brief allusion to the importance of regard to constitutional health on the part of parties contracting marriage. "It is positively startling," said Mr. G. in referring to certain special health returns, "to observe in them statistics of the strongly hereditary character of good and indifferent constitutions." He finds reason to believe that marriages of unhealthy men and women are not infrequent; and he adds: "These returns seem to show that the issue of such marriages are barely capable of pushing their way to the front ranks of life. All statistical data concur in proving that healthy persons are more likely to have healthy progeny; and this truth cannot be too often illustrated, until it has taken such a hold of the popular mind that considerations of health and energy shall be of recognized importance in questions of marriage, so much so as the more immediately obvious ones of rank and fortune."

Mr. Galton is quite right, and the truth which he thus puts forward is one of the highest importance. If people would only remember that for the most part they may choose whether their families shall be healthy, active and energetic, or not, much of the helplessness and misery which now afflict the nations of the earth would disappear.

HOW TO AVOID COLDS.—An editorial in the *British Medical Journal*, on catching cold, concludes thus: "The practical considerations which are the outcomes of this review of pathology of colds are these: Never wear wet clothes after active muscular exertion has ceased, but change them at once; to meet the loss of the body heat by warm fluids and dry clothes; to avoid long sustained loss of heat which is not met by increased production of heat; to increase the tonicity of the vessels of the skin by cold baths, etc., so educating them to contract readily on exposure, by a partial adoption indeed of the "hardening" plan; and to prevent the inspiration of cold air by the mouth by some protecting agent, as a respirator. We can readily understand how a respirator should be an effective protection against winter bronchitis in those so disposed.

USEFUL INFORMATION.

Reduction of Obesity.

An exchange says: "Obesity is made the subject of an interesting article in the *Journal des Connaissances Médicales*, by Dr. Corlieu. Dr. Banting's system of cure consists, as is pretty generally known, in abstaining from bread, butter, milk, sugar and potatoes; taking about five ounces of beef, mutton, fish, or bacon, for breakfast, with a large cup of tea without either milk or sugar, and with an ounce of biscuit or toast; for dinner, about six ounces of any fish except salmon; of any kind of meat exclusive of pork, and of any vegetables save potatoes. Game, fowls, pudding, champagne, port and beer, forbidden.

Another method is described in the article before us as tried by a physician, Dr. Philbert, who was himself the patient. At the age of twenty-six he weighed three hundred and ten pounds, and measured four feet ten inches around the abdomen. His sleep was heavy, his pulse irregular at seventy-two per minute, his appetite and digestion were good. Having placed himself under the care of Dr. Schiudler, at Marienbad, Bohemia, he treated him as follows: Get up at six in the morning; from half-past six to seven take three glasses (six ounces each) of the Krentzbrunn spring; from half past seven to eight, two boiled eggs and a cup of tea, and a small roll; from nine to ten, a vapor bath daily, the first perspiration being followed by friction with a gloved hand and a cold *douche*; the second by rubbing with a soft flesh-brush; the third, by flagellation with a bundle of poplar twigs with their leaves on, then a second *douche* of cold water. On leaving the bath rubbing the body with vinegar. After the bath, a walk. At eleven A. M., two dishes of meat or fish, one of vegetables, boiled fruit without sugar, half a bottle of wine, and two small rolls. From noon to six a permanent stay in the forest surrounding the town, walking as much as possible without fatigue. At six, a dish of cold meat, boiled fruit as above, half a bottle of wine and a roll of bread. A walk after this dinner. At eight, shampooing with soap; half an hour later to bed. Morning and evening, five alkaline pills.

The treatment lasted six weeks, at the end of which he had lost thirty-five pounds. He then continued the cure at home, with the Marienbad waters for a fortnight, and afterward went to Fontainebleau in order to eat two pounds of grapes gathered on the spot, every morning fasting. At the end of two months he had reduced his weight to two hundred and fifty-six pounds, and has since come down to one hundred and eighty pounds, enjoying excellent health.

NATURAL ANTISCORBUTICS.—General Sherman says that the *agaya Americana*, or Spanish bayonet, the fruit of the common prickly pear, and the succulent leaves of some of the varieties of the cactus that abounds on the deserts of Texas, New Mexico and Arizona, furnish excellent specifics for that horrible disease, the scurvy.

Structure of a Cow's Horn.

It is very frequently the case that in the commonest, most uninviting of objects, we may see (if we like) beautiful examples of engineering skill. A few days since, says Mr. Frank Buckland in *Land and Water*, I was inspecting the large tanneries of the Messrs. Hamlyn at Buckfastleigh, on the River Dart, Devonshire. In one of the back yards was a mountain of the skulls and horns of cows of all sorts and kinds. Here there was a treasure worthy of investigation; so I got on to the mountain of horns and skulls, and picked out some beautiful specimens which Mr. Hamlyn kindly gave me, in order to make sections, etc. I find that over the brain of the cow a strong roof of bone is thrown in the shape of an arch, so as to form a substantial foundation for the horns. This roof is not solid, but is again strengthened below by a series of bony arches, that are so distributed as to form a series of hollow chambers, thus forming a structure uniting strength with lightness.

The problem now is, how to fasten the horn on each side on to this buttress. The horn itself must of course be formed of horn proper, i. e., hardened hair. In the rhinoceros, we find a horn composed entirely of a solid mass of what is really a bunch of hair agglutinated together; but this kind of horn would have been much too heavy for the cow's convenient use. What is to be done? Why, hollow out the center of the horn of course; but stay—this will not do, because how is the horn to be supplied with blood-vessels?—in fact, how is it to grow? Let us see how it is done by the great Designer.

Cut the horn right across with a saw, and you will find inside another horn, only made of bone. If the section is made about one-third of the way down the length of the horn, you will be able to pick out a piece of bone in the shape of a cone, on which, or rather round which, the horn proper has shaped itself. This bone fits the cavity with the greatest accuracy; it is as light as the thinnest paper, and yet as strong as a cone of tin. It is everywhere perforated with holes, which in life contained the nerves, the veins and arteries, and we know a cow has all these in her horns; nerves proved by the fact that cows do not like their horns touched, and that they can scratch a fly off their hides with the top of the horn; arteries and veins, proved by the fact that a horn when broken will bleed, and that the horn of a living cow feels quite warm when held in the hand, besides which the nerves and arteries form a union between the internal core of bone and the external covering of horn proper.

If we now cut the rest of the horn into sections we shall find that the inside of the bony part is really hollow, but that very strong buttresses of bone are thrown about every inch or so, across the cavity of the horn in such a manner as to give it the greatest possible support and strength. I have cut a cow's horn and skull into several sections to show these buttresses of bone, and now that the preparation is finished I have another specimen to show that there is design and beauty in all created objects.

Chinese India Ink.

Although the Chinese prepare their ink from the kernel of some amygdalaceous fruit, yet, by the aid of our present chemical appliances we are able to produce a composition in no way inferior to the best Chinese ink, by the adoption of a formula which is given in Riffault's treatise on the "Manufacture of Colors." The following is the formula:

Calcined lampblack, 100 parts; hoghead shale black, in impalpable powder, 50 parts; indigo carmine, in cakes, 10 parts; carmine lake, 5 parts; gum arabic (first quality), 10 parts; purified oxgall, 20 parts; alcoholic extract of musk, 5 parts.

The gum is dissolved in 50 to 60 parts pure water, and the solution filtered through a cloth. The indigo carmine, lake, lampblack and shale black are incorporated with this liquor, and the whole ground upon a slab with a muller, in the same manner as ordinary colors; but in this case the grinding takes much longer. When the paste is thoroughly homogeneous the oxgall is gradually added, and then the alcoholic extract of musk. The more the black is ground the finer it is. The black is then allowed to dry in the air until it has acquired sufficient consistency to be molded into cakes, which in their turn are still further dried in the air, out of the reach of dust. When quite firm these cakes are compressed in bronze molds, having appropriate designs engraved upon them. The molded ink is then wrapped in tinfoil, with a second envelope of gilt paper. The ink which has been prepared in this manner possesses all the properties of the real Chinese article. Its grain is smooth; it flows very well, mixes perfectly with many other colors, and becomes so firmly fixed to the paper that other colors may be spread over it without washing it out.

USEFUL INFORMATION.—It is sometimes useful to know how to dissolve silver without attacking copper, brass or German silver, so as to remove the silver from silvered objects, plated ware, etc. A liquid for the purpose is simply a mixture of nitric acid with six parts of sulphuric, heated in a water bath to 106 deg. Fah., at which temperature it operates best. By this means the old silver attached to plated ware, old daguerreotype plates, etc., may be removed and saved without necessity for wasting acids in dissolving a large amount of useless metal.

Domestic Economy.

How to Cook Turkeys and Chickens.

ROAST TURKEY.—A turkey should be well singed and cleaned of pin feathers; then draw the inwards. Be sure you take everything out that is inside. Dip the turkey into cold water; clean the gizzard, liver, heart and neck; let all soak one hour if you have time. Wash all very clean; wipe the turkey very dry inside and out. Make a dressing of two cupfuls of bread crumbs, one teaspoonful of salt, two large spoonfuls of sweet marjoram, two spoonfuls of butter, one egg and mix them well together. Cut the skin of the turkey in the back part of the neck, that the breast may look plump; fill the breast with the force-meat and sew it up. If you have any more force-meat than is required for the breast, put the remainder into the body and skewer the vent, tie the legs down very tight, skewer the wings down to the sides, and turn the neck on to the hank with a strong skewer. Baste with salt and water once, then frequently with butter; fifteen minutes before dishing, dredge with a little salt and flour, and baste with butter for the last time. This will give a fine frothy appearance and add to the flavor of the turkey.

To make gravy, put the gizzard, neck and liver, into a saucepan with a quart of water, a little pepper, salt and mace; put it on the fire and let it boil to about half a pint. When done, braid up the liver very fine with a knife, and put it back into the water it was boiled in; then add the drippings of the turkey and a little flour, and give it one boil, stirring it all the time. Dish the gizzard with the turkey. Allow twelve minutes to a pound for the time to roast a turkey. A turkey weighing ten pounds requires two hours to roast with a clear fire, not too hot. Turn the spit very often.

Boiled turkey is prepared the same as for roasting, except in the dressing. Put in pork, chopped very fine, instead of butter. In trussing, turn the wings on the back instead of the sides, as for roasting; flour a cloth well, pin up the turkey tight, put it into boiling water where one or two pounds of salt pork have been boiling for some time; let this boil with the turkey; and dish the pork with the turkey on a separate dish, with some parsley. Serve with oysters or celery sauce. A turkey weighing eight pounds requires an hour and a half to boil.

ROAST CHICKENS.—Dress and roast the same as a turkey. A pair of chickens weighing six pounds require an hour and a half to roast. Make the gravy the same as for a turkey, except the mace, which is to be omitted.

BOILED CHICKENS.—Dress and boil the same as a turkey. Some cooks do not stuff boiled chickens or turkeys; but the dressing adds as much to the boiled as to the roast. Pork boiled with chickens is very necessary. A pair of chickens require from one to two hours to boil, depending upon the size and age.—*Ohio Farmer.*

BLOWING MEAT.—Dr. Yeld, medical officer of health for Sunderland, England, has presented a memorial to the health committee of that town against the "blowing and stuffing of meat." The practice of "blowing" is described as follows: "A tube or pipe is thrust under the skin of the meat, and the butcher or dresser then blows the foul air from his own lungs into the cellular tissue of the meat, the effect being that a deceptive appearance of plumpness or fatness is given to the meat, and in many cases it becomes tainted with the smell of rum, tobacco, etc." This is pleasant for consumers of meat, and where ignorance is bliss, it is perhaps folly to be wise; and now that public attention has been called to the "blowing" practice, it might perhaps be as well for butchers to meet the wishes of the fastidious so far as to use a pair of bellows for the purpose of giving a graceful contour to the carcasses of animals they kill. Even for their own sakes they will act prudently by discontinuing the use of their lungs in the process.

CHOCOLATE CARAMELS.—Take one pound of sugar, one-fourth pound of chocolate, one tablespoonful of milk, one also of molasses. Grate the chocolate and mix with sugar, etc. Put the mixture in an iron skillet on the back part of the stove, where the heat will slowly melt it. Cook slowly, stirring it well. To ascertain when done, take a little in a spoon and drop it in a cup of water; if done, it ought to sink in a solid mass, and in a few minutes be firm. When you have decided that it is cooked enough, grease a long cheese-cake tin with butter; pour in the mass and spread evenly. Before too cold, cut in small squares.

BREAKFAST INDIAN CAKE.—Take as much meal as may be required, scald it partially; then take some drippings of lard and warm water—melt the fat with it; then take the meal and mix it with milk to the proper consistency; add a little salt and a beaten egg, or the egg may be omitted; bake on the griddle, and you will have an excellent cake.

WATER CAKE.—Take four cups of sifted flour, two cups of white sugar, half a cup of butter, two eggs, and one cup of water. Turn the water over the butter, stir the sugar into it, add the eggs well beaten. Dissolve a small teaspoonful of saleratus in a little boiling water; stir it in; mix two spoonfuls of cream of tartar with the flour. Nutmeg, lemon or mace for the flavoring.

TABLE OF CONTENTS.

EDITORIALS AND GENERAL NEWS.—Improved Current Water Wheel; More Rain Wanted; Rosita Mining District, Page 1. Prospects; The Idaho Mine; Shell Mound, Oakland, 8. Hydraulic Mining in California; Mining Accidents; The Old Comstock, 9. Patents and Inventions; Shooting; Fatal Political Quarrel; Hawaiian Annexation, and other items of News, 12.

ILLUSTRATIONS.—McCarthy's Current Water Wheel, 1. Shell Mound, Oakland; Hydraulic Mining in California, 9.

MECHANICAL PROGRESS.—Cork as a Non-Conductor of Heat; Freezing Cast Iron from Phosphorus; Metallic Pens; Thick and Thin Saws; Belting and Gearing; Air Pressure in Wind Instruments; Springs as Motors; Pulling up Forest Trees by Steam; Computing the Speed of Gearing and Pulleys, 3.

SCIENTIFIC PROGRESS.—The Transit and its Probable Results; Peat Charcoal as a Deodorizer; The Telemeter in Surveying; The Development of Natural History and Science, 3.

MINING STOCK MARKET.—Thursday's Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of Stock Market for the Week, 4.

MINING SUMMARY.—From various counties in California and Nevada, 4-5.

GOOD HEALTH.—Washing Out the Stomach; The Hourly Death Rate; Simple Dyspepsia Remedies; Nelson's Treatment of Boils; Red Wall Paper; Banners; Health and Marriage; How to Avoid Colds, 7.

USEFUL INFORMATION.—Reduction of Obesity; Natural Antiseptics; Structure of a Cow's Horn; Chinese India Ink; Useful Information, 7.

DOMESTIC ECONOMY.—How to Cook Turkeys and Chickens; Blowing Meat; Chocolate Caramels; Breakfast Indian Cake; Water Cake, 7.

MISCELLANEOUS.—The Big Fish Mining Theories; The Iowa Hill Canal; Cose—The New District; Removing Hair from Hides, 2. Development of the Iron Interest; Bartlett Creek; Columbia District; New Oregon Mines; Pancake Mountain Coal; City Mining; Prospecting Northwest; The New Mine; Napa County Mines; Of Doubtful Practicability; Bull Run and Cornucopia; Fastening Iron in Stone; Marking Tools, 6. Novices and Adonis Soil; Paradise Valley; Landscape Gardening; Crude Way to Test Sulphurets; Groom District; Levee Law Amendments in Political Code; Relief District, 10.

[Business Notice.]

Mining and Scientific Press,

A VALUABLE WEEKLY FOR

Miners, Mechanics and Manufacturers
on the Pacific Coast.

Volume XXX of this first-class, standard journal commences with the year 1875. Its proprietors, having the successful experience of ten years publication of the Press, have no hesitation in saying that for the ensuing year the paper shall, in keeping with the times, reach a higher mark of merit than ever before.

With our own printing press, folding machine,

Able Editors, Correspondents,

And skilled workmen in different departments of our now extensive and growing establishment, we mean to print a journal throughout the year, which all citizens, whether patrons or not, may be proud of seeing published and supported on this side of the continent.

No kindred journal in America furnishes more real

Fresh, Novel, Interesting Information

In its volumes than the MINING AND SCIENTIFIC PRESS. We have the

Largest Mining Field in the World

To report from. It embraces the largest variety of mines and mining; methods of working; and more numerous wonderful discoveries than any

other section of the globe. It is the birth place of many of the

Latest and Best Inventions in Gold, Silver and Labor Saving,

With brief, reliable, well chosen and prepared editorials; varied and condensed correspondence and selections; tables and statistics arranged for ready reference,

Superior Illustrations,

Of local and general interest to its readers, it forms a weekly journal of individual character and unrivalled worth to its intelligent and industrial Patrons at home and abroad. It is the

Leading Mining Journal of America,

And in its practical, interesting and substantial make up, it is unrivalled by any mining or mechanical journal in the world.

Home Manufactures and Home Inventions

Will be constantly encouraged. Both help to build up the brain and material wealth of the country. They are kindred to our individual enterprise. Our interests are mutual with all home artizans and producers. Where on the face of the globe do INVENTORS and MANUFACTURERS either NEED or DESERVE more encouragement?

Its Value to the Community,

In disseminating important information; dissipating false notions; checking expensive follies; instigating important enterprises; by wise counsel and scientific direction, enriching the rewards of honest labor, we are annually saving and adding

Millions of Dollars

To the products of our country. The Press has already

A Large Circulation,

And is deserving of more universal patronage from those whose interests it specially represents. This sparsely populated portion of the Union is a difficult one for publishers to present the claim of their journal in to all who should subscribe. In these times of seemingly cheap (but largely, trashy and worthless) journalism, it is desirable and proper that those who know the real merits of a faithful journal should

Speak and Act in its Favor.

We shall not spare our efforts to make sound and improved issues, maintaining constantly the rights of all, and forwarding the material and intellectual rights of our patrons, and of our sturdy, progressive community.

Necessarily, scientific and mining publications generally are costly and high priced, but considering the size, character and location of our publication, our rates are favorable for so valuable a print.

We invite correspondence from all sections.

Subscriptions, payable in advance, \$4 a year. Single copies, postpaid, 10 cents.

Address,

DEWEY & CO.,

PUBLISHERS, No. 224 Sansome St., S. F.

A QUERY.—Would it be practicable to construct an apparatus which would automatically imitate the sounds of a telegraphic instrument? Some who read this may be already aware that messages can be sent very rapidly by means of perforated patterns, punctured to correspond to the dots and dashes used in telegraphy. If some inventor will be ingenious enough to apply this principle, or some other, in such a way as to get up a self-acting sonnder which will repeat any given message that may be arranged for it, imitating the sounds made by a good operator; such a sonnder could be made very useful to students in telegraphy. By its use students could, at their own homes, soon become familiar with these sounds. It would greatly aid in removing one of the chief difficulties in the way of becoming a "sonnder" operator.

A CLEAN-UP at the Chile Gulch hydraulic, Calaveras county, last week, realized \$21,000.

The Idaho Mine.

The Idaho mine, Grass Valley, is owned by a few people and worked on strict business principles as all mines should be. It is not known in the stock market, and is not listed in the Board. For this reason no quotations of its value appear in the newspapers, and very little is heard of it except reports of progress in the Grass Valley newspapers. The mine is owned by a "close corporation," has its offices in Grass Valley, and is not known on California street. The 35-stamp mill, hoisting works and machinery are the best in the district, and the mine is in a generally prosperous condition. The mine is a sample of many others in this State, worked by private companies, which greatly increase the billion product, and of which no record is made of profits. In the published statement of dividends, etc., each year, no mines are mentioned except those on the stock list, and mines like the Idaho are totally ignored. Nevertheless, the Idaho has paid from 1869 to 1874 the sum of \$1,602,750 in dividends, making a profit of 517 per cent. during that time on the capital stock. Since 1869 there have been 65 dividends paid, as follows: In 1869 11 dividends were paid, equal to \$170,500, or 55 per cent. on the capital stock. In 1870 the mine paid seven dividends, equal to \$37,500, or 12 per cent. In 1871 it paid 12 dividends, equal to \$232,500, or 75 per cent. In 1872 it paid 11 dividends, equal to \$162,750, or 52½ per cent. In 1873 it paid 12 dividends, equal to \$682,000, or 220 per cent. In 1874 it paid 12 dividends, equal to \$317,750, or 102½ per cent. This makes a total of \$1,602,750 in dividends, or 517 per cent on the capital stock in six years.

There are few mines which can show a better record than this when the percentage of profit is considered. There are only 3,100 shares in all, and the owners realized a profit this year of \$102.50 per share. The report of the officers of the mine as published in full in the Grass Valley Union is quite interesting, as showing the relative expenses and profits of working the mine. During the year they crushed 28,801½ tons of rock, of which 1,942½ tons came from the 400 level; 1,886½ tons came from the 500 level; 5,581½ tons came from the 600 level; 16,433½ tons came from the 700 level; 1,594½ tons came from the 800 level, and 963 from the shaft. This gave a gross yield of 36,169 ounces of gold, \$631,190.56—217 tons of sulphurets, \$1,600; specimens, \$38.50; gross yield of tailings, \$10,959.25; gold from old copper, \$692.39. Total, \$664,811.20. Giving an average of \$23.40 per ton.

The superintendent states that during the year they have driven 1,149 feet of drift. This amount of drift has opened up more ledge than they have worked out, and he estimates that they have four years work of pay ore in sight. The following is a summary of receipts and expenditures:

EXPENDITURES.	
Mill and mining.....	\$233,662.20
Sulphurets account.....	4,436.50
Tailing do.....	1,288.50
McDougal concentrator.....	293.01
Burleigh drill.....	11,667.20
New pumping works.....	25,001.41
Repairing old shaft for pump.....	9,186.86
New steam pump for 200 level.....	1,685.02
Sinking main shaft.....	23,375.53
General account.....	24,270.99
Total expense of working mine.....	\$334,767.58
Dividends \$102.50 per share.....	317,750.00
	\$652,517.58

RECEIPTS.	
Cash on hand.....	\$ 10,297.10
31,167 ounces bullion.....	631,190.56
Sulphurets, worked and sold.....	19,243.35
Percentage from tailing.....	5,587.13
Pan rent.....	1,288.50
Old copper.....	992.89
Lease of surplus water.....	400.00
Specimens sold.....	38.50
Old rope.....	15.00
Total receipts.....	\$699,023.03
Expenditures.....	652,517.58
Cash on hand.....	\$ 16,505.45

On the mill and mining account the principal items were \$15,605 for surface labor, \$123,912 for underground labor, \$9,312 for foundry work, \$21,522 for lumber, \$4,055 for powder and fuse, \$5,220 for candles and oils, \$3,116 for quicksilver and \$6,000 for Superintendent's salary.

They sold 153 tons of sulphurets, and worked 64 tons, the latter costing \$1,600 to work by chlorination process. From the whole they got \$19,243. The Burleigh drill cost them \$11,567 of which the machinery cost \$7,800, freight and commission \$1,103, and masonry foundation \$2,168. The new pumping works cost \$25,000, of which the foundry work cost \$16,764.

Repairing the old shaft cost \$9,186, of which \$7,217 was spent for labor; sinking the new shaft cost \$23,375, of which \$16,886 was for underground labor and \$2,652 was for surface labor. The State and county tax on the mine for the year was \$15,200.

The receipts from all sources, according to the report of the Secretary, were from December, 1873 to December 1874, \$658,725, which,

with a balance on hand December 1st, 1873, shows assets for the year of \$669,023. The total expenses including dividends for the year, were \$652,517, leaving a balance in the treasury December 1st, 1874 of 16,505. In these expenditures are included 12 dividends amounting in all to \$317,750 for the year.

In reviewing the operations of the mine for the year, it will be seen that the yield of the rock has not been so much nor the dividends so large as last year. Still it has been very good, and the dividends very handsome. The pumping capacity of the mine has been increased, and in carrying that out the old shaft has been straightened and retimbered, and this work is still in progress. The engine is 20 inch diameter and 42 inch stroke. The surface machinery is all set on solid masonry, and all its parts are deemed sufficiently strong and capable of standing any work that may be required of it for many years. The Superintendent says: The underground work has been pushed ahead with due diligence, and having in view the importance of keeping the mine well opened, work has been constantly going on in the drifts and in the main shaft. The shaft is down 75 feet below the 800 level. The ledge is somewhat broken up, thus rendering it necessary to carry away large shafts, as well as to make it more expensive. The quartz seems to be improving, and it is thought it will form a solid ledge before reaching the 900 level. The 800 west level is in 116 feet from the shaft, but little rock has been taken from the backs. This is an average quality of rock. Also the 800 east is of average grade ore, and the drift is in 109 feet from the shaft. The 700 west drift is in to within 35 feet of the Enreka mine, and a few months more will exhaust the backs. The 700 east drift is in 424 feet from the shaft, and the backs are worked through to the 600 level 233 feet from the shaft. The 600 south drift is in 803 feet from the shaft, or 322½ feet from the split. The ledge is exhausted in the drift, and it is low grade ore in the backs. The north branch is in 421 feet from the split, and 901½ feet from the shaft. The ledge has been very small, it is now opening out larger, but it is low grade ore; however from indications it ought to come in better. The rock in those backs is good mill rock, and it is worked through to the 500 level 341 feet from the shaft. The 500 backs is of an average quality; they are not yet worked through to the 400 at any point. The 400 is exhausted.

At the annual election held on the 21st of December, the following Trustees were elected for the year: Edward Coleman, John C. Coleman, M. P. O'Connor, Thomas Findley and John Polglase. The Board organized with the following officers: Edward Coleman, President and Superintendent; Geo. W. Hill, Secretary; Thomas Findley, Treasurer.

Shell Mound, Oakland.

Some two miles to the northwest of Oakland city hall, a few rods from the shore of the bay, on the farm of Mr. Wiard, stands an aboriginal mound. Well-grown willow trees effectually conceal it from view until you arrive quite near it. The accompanying sketch was taken when the tops of many of the trees on the south side were cut away. These have now so luxuriantly grown as to embower the tumulus, and shut out the view on the side of approach. It is called the "Shell Mound," from the fact of its being composed chiefly of marine shells and some gravel. It rises a sharply defined pile from the surface of a uniformly level plain of rich, alluvial soil. Without exact measurement it is estimated to be near thirty-five feet high. It is a circular, conical pyramid, with a truncated or flat summit, which measures 150 feet in diameter, and 300 feet at the base. Bones, skulls, stone mortars and charcoal, have been found in and about it.

That it owes its existence to the barbarous energy of human beings is self-evident. Abbo Domenico, speaking of Indian mounds on the Pacific coast, says they are often made from the adjacent soil, and hence near them is observed wells or pits from which the earth has been taken to erect them. Such an explanation does not apply to the Oakland mound, for there are no pit holes in its vicinity, and if there had been, which by the agency of the elements and time became filled up, that alluvial soil could not furnish the shells of which the mound is mainly composed.

Shell mounds are numerous on the Pacific coast, and they abound in profusion in Denmark. Danish archaeologists call them "kjokkenmoddings," or "kitchenmiddens," and regard them as the accumulated remains of the repasts of by-gone inhabitants. We know not how the people slept, but these crumbs tell us what they ate and where. Such mounds have grown into existence by accident and without object. A like "kitchen midden" keeps subordinate company with the subject of our sketch, only a few rods east of it. This is a beautiful, round topped knoll, some 12 feet high and 400 feet basic diameter. On this most reliable spot of always moist, mellow mould, Mr. W.'s dwelling-house stands surrounded with choice shrubbery.

They are digging away and otherwise preparing to put in place at the Consolidated Virginia hoisting works a new engine for forcing air down to the mine.

Hydraulic Mining in California.

No. 6.

The Chimney.

The advisability of extending the tunnel well into the basin before "tapping" the latter cannot be disputed. If a shaft or incline has been sunk to the depth of the channel or basin, the terminus of the tunnel can be decided upon according to the knowledge gained. Whenever this point is reached, it will be necessary to pierce the bed-rock intervening between the terminus and the gravel deposit in the channel, by a "chimney"—either a vertical shaft or a slope. This chimney must be started in such a direction as to strike the bottom of the shaft or incline. Should water have collected in the latter it must be removed by pumping before a connection is made. Want of care in this matter has caused much lamentable loss of life.

Chimney Without Shaft.

Should, however, no shaft or incline exist, and should this condition of the gravel bed overhead be unknown, the greatest care must be taken in making the attempt to break through.

As before remarked, great bodies of sand lie in the sloping rim-rock, before the solid bottom gravel is reached. This sand is in connection with loose gravel deposits overhead, and becomes quick under the great pressure of water which always exists in deep gravel deposits. (See Fig. G.) Whenever these sand patches are entered without the greatest precaution, immense rushes of water, sand, and loose gravel will occur, filling often the largest tunnels in a few minutes. There are cases on record where the labor of two or three years was lost, the greatest portion of the tunnel being necessarily abandoned, and a new direction, to the right or left, pursued. When, therefore, the attempt is made to run up a chimney from the terminus of the tunnel into the unexplored channel above, the work should be commenced in the right or left of the terminus, and be continued on a convenient slope. The experienced miner will know, whenever the water increases in the seams of the rock, or when the seams turn yellow, or the rock changes to a softer stratum, that the basin or channel may be only a short distance above. When these signs occur, it is advisable to drill a hole far enough to test the thickness of the rock intervening between the chimney and the channel. Should the drill pierce the rock, it is easy to insert a thinner and longer iron rod to feel the deposit above the bed-rock. If hard gravel is struck all will be safe, and the chimney can be continued without any apprehension; but if water and sand are found, and the iron rod enters readily for 5 or 6 feet, it will be better to abandon the chimney at once, and continue the tunnel. The presence of sand and water, or quicksand, indicates that the depth of the channel is not reached, and that the most valuable gravel deposits lie deeper, and at the same time forewarns the miner of a great danger, a rush of quicksand and loose gravel.

The diagram given herewith, representing a section of sloping rim-rock, and the different deposits as they occurred in fact, will explain itself.

The chimney, if hard gravel is reached, should be continued, as before stated, on a slope, as in this way the work can be more safely done than in a vertical shaft. This consideration may be of little importance, so long as the ground is hard and strong, but in softer strata, surcharged with water, a slope offers the only chance to proceed with safety to a certain point. When this point is reached, and a further progress barred, it is best to secure the terminus of the chimney in such a way that the water can drain off, without giving the sand, or loose gravel, a chance to run. After this careful survey must be made to ascertain the exact spot where a shaft from the surface down will strike the terminus of the chimney. This is an easy matter when the tunnel is straight.

Shaft.

A shaft with square section, (say 4 by 4 feet,) to permit timbering, must be commenced and worked down in the usual way, as far as circumstances will permit. If the drainage established through the chimney is sufficient to free the shaft from water, it will be comparatively easy to go through sand and gravel and connect shaft and chimney; but if this drainage cannot be established, or is not adequate, even with additional hoisting of the water by windlasses and buckets, it is best to procure an artesian borer, and to make thus a connection between the bottom of the shaft and the chimney. (The character of the ground excluding the existence of large pebbles or boulders, an artesian borer can be used to advantage.) After this the shaft can be brought down, but must be secured firmly against side pressure by good framing and planking.

First Washing.

The connection once made between shaft and chimney, sluice boxes may be laid through the tunnel, and the first washing of "dirt" may commence. This begins by removing the upper sections of timber out of the shaft, widening its mouth by pick, shovel, and water, and tumbling and running the "dirt" and water into it, always, however, taking care not to choke the shaft or chimney. This process is

continued downward, in the shape of steps, or terraces, as security against cavings or slides. It must depend on the depth of the shaft, as well as on the greater or less safety of the ground, whether a larger or smaller opening of the shaft is to be made, since dangerous cavings may occur in spite of all precautions. In this way an opening must be made to permit the use of water under pressure. It must be left to the manager of the mine to shape the chimney in such a way that an easy and uninterrupted discharge in the sluice boxes is secured.

If the main tunnel is to be continued farther it will be necessary to leave enough space between the starting point of the chimney and the face of the tunnel to admit blasting operations. At the same time precaution ought to

To avoid these dangers working in benches is resorted to, (see page 7), and the washing away of the upper strata thus serves three beneficial objects: first, in producing the pecuniary means in support of other works to be carried on; second, in lessening the depth of the shaft to connect with bed-rock tunnel; and third, in leaving a "bench" which, under all circumstances, will be necessary in a deep gravel mine.

—Condensed from an article by Charles Waldeyer, in the last Annual Report of the U. S. Commissioner of Mining Statistics.

A New Volume.

With this number commences Volume XXX of the MINING AND SCIENTIFIC PRESS. The pa-

SHELL MOUND, OAKLAND.

be taken to protect the blasters in the tunnel from any accident arising from the possible blockade of the sluice boxes or tunnel, and the only safe expedient will be to have not only a strong barrier between the blasters and sluice boxes, but also to have an independent way for ingress and egress. This may be secured by

Fig. VI.

A, quicksand; B, red gravel, (firm); C, loose gravel; D, moraine; E, blue gravel; F, bed-rock.

widening the chimney sufficiently to admit a strong water-proof box with a ladder, by which means the miner can reach the surface of the ground, without interference from either the washings or cavings of the gravel from above, or any blockade in the tunnel below.

It will be seen that the existence of a shaft

Fig. VII.

Gravel-bank, with three drifts; A B, bed-rock tunnel.

or incline, before the connection between the terminus of the tunnel and the basin or channel, is of great importance. If an incline exists, great facilities are offered to employ hydrostatic power from the lower part of the incline, as soon as a moderate opening is made to the surface.

Upper Workings.

Many mines are situated so favorably that the upper strata can be worked without any expensive bed-rock tunnel. In such cases it will be advisable, if circumstances permit, to commence the working of the upper strata at once, particularly if the gravel deposit has a thickness of two or three hundred feet. In this case a very useful and necessary work can be accomplished pending the construction of the deeper bed-rock tunnel; and perhaps a part, if not all, of the cost of the latter may be earned.

When the gravel bank rises to a greater height than 125 or 150 feet, the work in a hydraulic mine becomes very dangerous, as the momentum of any mass of matter falling from the high bank will carry it far into the mine, endangering life and property.

The Old Comstock.

The fortunate owners of some of the mines on this famous lode, who familiarly apply the "pet name" which heads these remarks, to the most wonderful lode in the world, have of late become more attached to it than ever. The "Old Comstock," so much belied, so badly misrepresented; the subject of thousands of articles and hundreds of sermons intended to induce people to abandon mining; the Old Comstock, which has held its grip through all, is coming out gruder than ever. Although the figures—which are never supposed to lie except in mining matters, when they are always supposed to misrepresent—show that the profits of the Comstock mines since the lode was discovered have been enormous. Every time the stock market fell we were told that the mines there were worthless; still the owners of the mines went on working and sinking regardless of all rumors or reports. They had faith in the Old Comstock, and their faith has been well repaid. They sunk shafts and winzes, ran levels and drifts, made inclines and tunnels, built hoisting and pumping works, put up mills and buildings, and continued to prospect and open up their mines in the face of all sorts of difficulties. The results have been most magnificent; their labor has been rewarded a thousand-fold.

The mines which have "struck it" have made fortunes for their owners and encouraged other mines to further development. The smallest and most insignificant mine on the lode may strike rich ore any day, and become famous. Some of the mines have worked out their ore bodies and are working on for others. Some, again, have been unprofitable and have been kept running by assessments. But still, when we compare the assessments with the dividends, as a whole, the dividends have a magnificent balance in their favor.

Aside from all questions of individual profit, there is one question which is seldom thought of, but which is of very great importance. If the mine simply paid expenses it would yet be beneficial to the country to have them worked. Thousands of persons are employed about them in one way and another, and immense amounts of money are distributed in the very channels where it is most needed, that is among the laboring classes. Why people should grumble because Mr. Jones, or Sharon or Hayward, or Ralston, or Flood & O'Brien, or a dozen others have accumulated large fortunes from these mines, we do not see. If these gentlemen have invested their money and received large profits, they are perfectly entitled to it. They are envied and abused by scores of people who wouldn't have the pluck to invest where there was not a sure thing, but who would like very much to come in for the profits without risk of loss.

They are not by any means the only ones who are prosperous on account of the profits of the mines. The farmers, millmen, teamsters, railroad men, foundrymen and mechanics of all kinds who are kept busy by the work on the Comstock, may be numbered by the thousands; of the fifteen or twenty foundries in this city which are now so busy, one-quarter would suffice if it were not for mining work. Artisans of all kinds are furnished with employment at good wages on account of these mines. A number of handsome and expensive buildings are going up in this city at present, which are being built with money made from the Comstock. These employ hundreds of men of different trades at fair wages and steady work. In fact the benefits are wide spread and general, causing prosperity in all branches of business and a hopeful feeling of its continuance.

Still, after all it has done and is doing, the Old Comstock promises us even more to come. It promises to increase its production and its dividends; to employ more men and to want more and heavier machinery; to turn the attention of the whole world toward the Pacific coast; to help build up the Queen of the Pacific more than it has ever done; to furnish capitalists with as much money as they want to invest in other directions; to give other countries a vast amount of experience in deep mining; to show other countries milling and mining machinery of dimensions and perfection never dreamed of; to call forth the inventive faculties of genius to aid in overcoming the difficulties attending mining on such a large scale and at such depths; to solve problems of ventilation by practice; to increase the resources of the coast; and to assist in bringing times of general prosperity to Nevada, California and the whole United States.

IT PAYS IN MORE WAYS THAN ONE.—It pays in more ways than one to take a good newspaper. If you read it, it is a benefit which lasts beyond death. If your family read it, they will be better companions for you and the world besides. It is a good representative of your community when sent abroad, and you can afford to support it for the value of its influence in the public weal.

The New Comer—1875.

How awkward the bookkeeper, the correspondent, and others who flourish the pen, feel in making the simple change of figures from '74 to '75! But it must be done; for time is "relentless" in small things as well as in more weighty matters. We accordingly make the imperative change, hoping that the "new broom"—1875—will really sweep a clean course for the PRESS, and that our intercourse with our subscribers and friends will be as pleasant when we remove it from the heading of our paper, as it is at the present time when we first place it there. We again wish our friends a "Happy New Year."

In Trinity county everything is dried up, and farmers and miners are waiting for rain.

Novices and Adobe Soil.

Eastern people before coming to California manifest a good deal of curiosity concerning our adobe soil; and one of the prominent points of their initiation into farm life here is becoming acquainted with this stubborn reality. We have on several occasions had inquiries from such parties for information on this subject. One of these, who confesses himself a novice in this respect, asks some general questions, which in answering we hope to benefit a class of careful, energetic, persistent men, who are well calculated to subdue this stubborn portion of our soil, and make the spots where it abounds places of enduring wealth.

The character of adobe soil varies materially in different localities; it is not safe, therefore, to accept any general system for treating this kind of soil. Particular care is needed in taking the soil when in proper condition to work. To work it when perfectly dry is simply impossible; and if it is plowed when too wet, and sticky, it becomes lumpy, hard, and altogether unmanageable. Our correspondent is probably acquainted with the characteristics of the heavy clay soil that forms much—and some of the best—of the farm land of the Atlantic States. He will find the adobe soil of California of the same character "only more so." Both require the same "catching" habit in working; deriving equal benefit from thorough cultivation, and being alike in their lasting qualities. In the East this kind of soil is brought up to a high state of cultivation by underground draining, subsoiling and fall plowing, leaving it exposed to the action of the frost during winter. This soil possesses in itself remarkable endurance in fertility, and will give a better return than any other for manure applied. It is not expected that the cultivators of adobe soil in California will, as yet, resort to underground draining and subsoiling; and they will not have the aid of severe frosts and repeated thawings; still, if they use the means within their reach they can subdue this soil, and bring it up to a perfect state of cultivation.

Our friend asks, "what grain and what fruit will grow on it?" We answer that when properly treated it will grow any kind of grain or fruit, but unless the condition of the soil is favorable when worked, the labor bestowed upon it will be extremely hard and unremunerative. Probably in the locality from which our correspondent writes—San Luis Obispo—the present condition of the soil would favor plowing. If he could put in a crop of wheat while the ground is in suitable condition, then early in autumn plow in the stubble, this would lighten up the soil beside furnishing a good supply of manure. If the wheat could be put in and get a good start, so as to cover the ground before the drying northerly appears, a good crop might, reasonably be expected; but if after seeding and before the starting of the grain, the heavy rains ensue, followed by dry north winds, then the prospect is discouraging. In regard to fruit, as in other products which we have mentioned, in connection with adobe soil, we, of course, cannot consider the various surroundings; these must be taken into account by the residents of the localities; but speaking of the character of the soil, merely, we say that it is especially adapted to apples and pears; and that under favorable circumstances, the small fruits, even strawberries, would do well on it.

In answer to the inquiry of our correspondent in regard to a work giving directions for planting and working nurseries, we would inform him that this coast is, so far as we can ascertain, destitute of reliable authority on this subject. Works that meet the wants of Eastern nurserymen in every respect, are not adapted to California. Our most successful nurserymen are those who have from the starting point adapted themselves to the peculiar wants of the country and have obtained their knowledge by experience. They have had much to learn, but they have learned it thoroughly, consequently judicious selections have been made in all departments; and the treatment of what they grow is, from the first, such as the soil and climate of the country require. No portion of the United States is better supplied at this important point, or has a better horticultural basis to build upon.

PARADISE VALLEY.—The *Silver State* says: There is not a mountain range in Humboldt county that has been at all prospected in which mineral bearing quartz has not been found. The mountains at the head of Paradise valley were supposed to be an exception to the rule, but recent developments in that locality prove the contrary. Last week Dan Muffley went in the range about four miles easterly from Camp Scott to cut cottonwood poles for John Byrnes. While at work on the hillside he noticed large quartz boulders in every direction, which led him to believe that there was a quartz ledge in the vicinity. With six hands he proceeded a short distance up the hill where he discovered a large ledge cropping out above the ground, and breaking off a piece with his ax was astonished to find that it was ore. Taking as much as he could conveniently carry he repaired to Byrnes', and informed him of what he had found. The result was a location of the ledge, and an assay of an average of the croppings, which was made yesterday by J. A. Algauner, assayer of the Humboldt reduction works. The certificates show that it contains \$55 45 per ton in silver, and Byrnes, who is a member of the Grand Jury is in a hurry to get home and ascertain more about the discovery.

Landscape Gardening.

Landscape gardening is an art which is but little understood in the Pacific States, generally speaking. We shall therefore try to make it not only interesting to the general reader, but profitable to those who may have such work in contemplation. Landscape paintings are always admired by people with any pretensions to refinement, and to paint a good and faithful likeness of a landscape the artist must possess the special gift of imitative ability. But to make a park or garden or lay out the ground of a private residence, no matter what the dimensions are, the landscape gardener must have good creative ability, being able to create something which will harmonize with the place and its surrounding.

Men or women who are fond of natural scenery often become bewildered from the extravagant beauties which the landscape may afford, and not unfrequently will they select one particular point which to their mind surpasses all others. To possess such a piece of landscaping in some special part of their grounds, would be a satisfaction indeed; but, great as would be the delight if this was accomplished, it often follows, through the criticism of others, more eminent in the profession, that sorrow takes the place of delight, and it often occurs in this way:

A sketch is perhaps made of that which we wish to possess, and although not marked by any special gift of imitative genius, yet it may be able to call to mind all the special features of interest that surround, or necessary to be remembered. After all the necessary preparations are completed, work is commenced; trees, shrubs, and plants are bought, rocks, soil and water are, perhaps, introduced, all to represent, as nearly as possible, the original picture. Work goes on and the required end may be attained to the entire satisfaction of the parties concerned; satisfied beyond a doubt, that they have accomplished much which is not only new and expensive, but forms one of the most unique pleasures grounds in the country; but alas for poor human nature, it depended too much on its own ability, not having had any previous knowledge of landscaping, I find that I have made a very great mistake. The introduction of such a piece of work on these grounds was entirely out of place. Finding now that it will be impossible to make such a work harmonize more improvements suggest. Keep your trees in moist sand until the ground is ready to receive them. The sooner a tree is "set out" after it has been taken from the nursery, the better. In ordering trees, instruct the nurseryman to trim ready for planting, and you will save freight as well as the vitality of the tree. These rules are good for all trees; but especially for the almond and peach.

Crude Way to Test Sulphurets.

Since it has been found that sulphurets will pay to save in milling process, and that the county abounds in this material, we give below a hint to prospectors in testing rock, which never fails. Several veins which have heretofore been considered of little value, on account of the large amount of sulphurets contained therein, and the ignorance of the holders of the way to test them, have been found to be immensely rich in gold. A new era is opened in mines here, and it will yet be found that these sulphurets are the ones for durability and wealth. This crude mode will not hold good in all cases, (in all kinds of sulphurets rock,) but will bring out more or less of the precious metal, if there is any in it: Put a piece of rock into the fire, say about the size of your fist, and heat it to a cherry-red, through-out, but do not get it to a white heat, as it will fuse and run; take it out of the fire and give it a gentle shower bath, so as to cool it off slowly, so too sudden a cooling will slack up the rock. When cool, examine the rock, and if it is rich it will generally show the gold. But for a surer test, pulverize it and "horn it out" in the usual way. This, perhaps, is not so sure a way as a test with acids, but acids are not always at hand in the woods with the prospector. After burning, as above, if it does not show gold, it will not be apt to do so with acids, as it scarcely, if ever fails to bring the color; that is, where the sulphuret is composed mostly of iron and sulphur, or arsenic, this test is good and will not fail. But where the sulphuret is copper (and iron) the test is not so good, because the copper fuses and carries everything that comes in contact with it, so if there is any gold with it, it will be covered or fused with copper.—*Tuolumne Independent.*

GROOM DISTRICT.—We understand that J. B. Osborn, who is largely interested in the mines of Groom district, will shortly commence the erection of reduction works at that place. Groom has been considered for years past one of the most promising undeveloped districts in southeastern Nevada. It is situated about 200 miles south of Eureka, in Lincoln county. The ores are mainly of the character treated by the smelting process. The starting of operations in Groom district is one of the fruits of the narrow-gauge railroad to Eureka. The ores of that section could not be made available at a profit so long as it was necessary to freight the bullion a distance of nearly 300 miles to the Central Pacific. The same is in a great measure true of Tybo district. Stages will do for localities which produce pure silver, but a railroad is requisite to carry off the bullion of important base metal camps.—*Eureka Sentinel.*

Levee Law Amendments in Political Code.

As the following amendments, lately made to the new code, are not generally known, we give them as important information to many of the readers of the Press:

INDIVIDUALS LIABLE TO DISTRICTS FOR ALL DAMAGES SUSTAINED BY REASON OF EXISTING OR CUTTING OF LEVEES.

[Amendment to Political Code.]
Sec. 3490.—Any person who shall cut, injure or destroy any levee or other works of reclamation in any district, is responsible for all damages which may be occasioned thereby to such levee works; and an action therefor must be brought in the District Court of the county, or either of the counties in which such levee works are situated, in the names of the trustees of the district. If there be no trustees then the action may be brought in the name of any landowner in the district. The amount recovered in such action must be paid to the treasurer of the county who must place the same to the credit of the district.

OCCUPANTS OF LANDS ON BANKS OF STREAMS LIABLE FOR DAMAGES. [Political Code.]

Sec. 3486.—Any person owning or occupying lands upon the banks of any stream where the lands lying back of such stream are lower than the bank thereof, is responsible for all damages which may be sustained by the owners or occupants of lower lands by reason of any cut or embankment made on the bank of such stream by the owner or occupant of the bank.

COUNTY AND INDIVIDUAL RESPONSIBLE FOR INJURY TO OR DESTRUCTION OF LEVEES BY MOBS OR RIOTS. [See Political Code and Amendment 73 and 74.]

Sec. 4,000.—Every county is a body politic and corporate, and as such has the powers specified in this code, or in special statutes, and such powers are necessarily implied from those expressed.

Sec. 4,452.—Every municipal corporation is responsible for injuries to real or personal property situated within its corporate limits done or caused by mobs or riots.

Sec. 4,453.—Actions for damages under the preceding section must be tried in the county in which the property injured is situated.

Sec. 4,454.—All actions herein provided for must be commenced within one year after the act complained of is committed.

BOARD OF SUPERVISORS AUTHORIZED TO PAY FOR DAMAGE CAUSED BY MOBS OR RIOTS.

Sec. 4,455.—On the certificate of the presiding officer or of the clerk of the court in which the judgment is rendered, the board of supervisors of the county or the legislative authority of the city must by ordinance direct and cause to be issued a warrant for the payment thereof on the general fund, and the same must be paid in its regular order, as other warrants of the municipal corporation are paid; and must, at the proper time, levy and cause to be collected a tax on the taxable property of such municipal corporation for the payment of such warrant within a period of not more than three years.

Sec. 4,456.—The plaintiff in any action authorized by this title must not recover if it appears upon the trial that the damage complained of was occasioned, in any manner aided, sanctioned, or permitted by his carelessness or negligence.

[Title IV, Chapter I, sections 4,452, 4,453, 4,454, 4,455, are made applicable to levees, by amendments to Political Code.]

Sec. 4,457.—The provisions of this title and chapter (Title IV, Chapter I) are applicable to cases where losses and other works of reclamation of any district are injured or destroyed by mob or riot; and the action brought for damages therefor must be prosecuted by the Attorney-General of the State in the name of the people of the State of California; and the amount recovered in such action must be paid to the Treasurer of the county, who must place the same to the credit of the district. All provisions of law inconsistent with the provisions of this section are repealed.

TO INJURE OR DESTROY LEVEES OR OTHER WORKS OF RECLAMATION, A FELONY, UNDER "AN ACT FOR THE PROTECTION OF CERTAIN LANDS FROM OVERFLOW," APPROVED MARCH 25TH, 1868.

Sec. 18.—Any person or persons who shall wilfully or maliciously, cut, injure or destroy, any levee or other work of protection built under the provision of this Act, or that may be in charge of said Board of Supervisors, shall be deemed guilty of felony, and upon conviction thereof be liable to any court of competent jurisdiction shall be fined in any sum not less than fifty dollars nor more than one thousand, or be confined in the State prison not less than one nor more than five years, or may be both fined and imprisoned, at the discretion of the court.

ACCESSORIES HELD AS PRINCIPALS.

Sec. 971 (Penal Code Amendment 73, 74).—The distinction between an accessory before the fact and a principal, in cases of felony, is abrogated, and all persons concerned in the commission of a felony, whether they directly commit the act constituting the offense, or aid and abet in its commission, though not present, shall hereafter be indicted, tried and punished as principals, and no additional facts need be alleged in any indictment against such an accessory than are required in an indictment against the principal.

Sec. 972.—An accessory to the commission of a felony may be indicted, tried and punished, though the principal may be neither indicted nor tried, and though the principal may be acquitted.

CONSPIRACY AND RIOTS, ETC., REFINED.

Sec. 182 (Penal Code).—If two or more persons conspire—

1st. To commit any crime; or

2d. Falsely to move or maintain any suit, action, or proceeding, etc. They are punishable by imprisonment in the county jail not exceeding one year, or by fine not exceeding \$1,000.

Sec. 405.—Any person who participates in any riot, is punishable by imprisonment in the county jail, etc.

Sec. 407.—Whenever two or more persons assemble together to do an unlawful act, and separate without doing or advancing toward it—such assembly is an unlawful assembly.

Sec. 408.—Every person participating is guilty of a misdemeanor.

Sec. 409.—Every person remaining present at the place of any riot, mob, or unlawful assembly, after warning, is guilty of a misdemeanor.

RELIEF DISTRICT.—It affords us pleasure to announce that work is to be resumed immediately on the Central Pacific mine, in Relief district. The Central produced considerable bullion at one time, and was almost on a paying basis when, owing to complications arising out of informalities in the articles of incorporation, work was suspended. M. H. Bailly, one of the principal owners, has let a contract to Stein, Tirrel & Co., to run a tunnel, now in 150 feet, 100 feet further on to the ledge. There is a mill attached to the mine, which of course will be started as soon as ore can be procured to run it. The ledge has been developed to a depth of 150 feet by a shaft, and at one time it produced ore that worked from \$800 to \$1,200 per ton in silver.—*Silver State.*

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and Retail, by DEWEY CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL.

MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their Respective Metals without Quicksilver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his speciality.

Price \$2.50 coin, or \$3 currency, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the miner, mill owner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE REDUCED TO \$5.

Nevada and California Processes of Silver and Gold Extraction, for general use, and especially of the Mining Public of California and Nevada, with full explanations and directions for all metallurgical operations connected with silver and gold from a preliminary examination of the ore to the final casting of the ingot. Also, a description of the general metallurgy of silver ores. 1864.

As its title indicates, this work gives a wide range of information applicable to all vein miners and workers in precious metals, affording hints and assistance of exceeding value to both the moderately informed and the most expert operator.

Price, \$5 in cloth; \$6 in leather—coin.

BY OTHER AUTHORS.

The Quartz Operator's Hand-Book; by P. M. Randall. 1871. Revised and Enlarged Edition. Cloth bound, 175 pages. Price, \$2.

Sulphurets: What They Are, How Concentrated, How Assayed, and How Worked; with a Chapter on the Blow-Pipe Assay of Minerals. By Wm. M. Barstow, M. D. 1867; cloth bound, 114 pages. Printed and sold by DEWEY & Co. Price, \$1; postage free. The best written work, and most complete work on the subject treated.

ANY OTHER BOOKS DESIRED will be furnished at the most reasonable rates by DEWEY & Co., Mining and Scientific Press Office, S. F.

Ayer's Hair Vigor

—FOR—
RESTORING GRAY HAIR TO ITS NATURAL VITALITY AND COLOR.

Advancing years, sickness, care, disappointment, and hereditary predisposition, all turn the hair gray, and either of them incline it to shed prematurely.

AYER'S HAIR VIGOR, by long and extensive use, has proven that it stops the falling of the hair immediately, often renews the growth, and always surely restores its color, when faded or gray. It stimulates the nutritive organs to healthy activity, and preserves both the hair and its beauty. Thin, shabby, weak or sickly hair becomes glossy, pliable and strengthened; lost hair regrows with lively expression; falling hair is checked and stablished; thin hair thickens; and faded or gray hair resumes their original color. Its operation is sure and harmless. It cures dandruff, heals all humors, and keeps the scalp cool, clean and soft—under which conditions, diseases of the scalp are impossible.

As a dressing for ladies' hair, the Vigor is praised for its grateful and agreeable perfume, and valued for the soft luster and richness of tone it imparts.

Machinery.

BALL'S SWEEPING DREDGE,

A NEW AND VALUABLE

CALIFORNIA INVENTION,

Has been very lately well proven by performing a job of dredging at the mouth of San Antonio Creek, at Oakland, Cal.

There is but this one machine that has ever had these improvements employed. It is an old machine, formerly built for another device, and is unfavorably constructed for Ball's improvements; yet this first temporary experimental machine has filled a scow of eighty-five cubic yards in sixteen minutes in unfavorable digging. For durability, digging hard material and fast work, it has a reputation (supported by leading engineers) as having no equal.

Testimonials and references will be given on application to the inventor, who is the sole owner of patents (excepting having made an assignment of the one machine now belonging to the Central Pacific Railroad Company) Having resolved not to sell any rights unless upon a basis of actual work performed by a machine built by myself for the purpose of fairly establishing the worth of the invention, I therefore offer to sell machines or rights on the following plan, which is warranting the capacity of the machine by actual work.

I will enter into an agreement with any responsible party to build and sell a machine, scows and tender, all complete, and right of all my improvements in dredging machines throughout the Pacific Coast for \$20,000, warranting the machine to dredge six cubic yards per minute (to fill a scow at that rate). \$20,000 will but little more than pay the cost of building the machine, scows, etc., all complete; therefore I am proposing to ask nothing for my patents unless my machine dredges more than six cubic yards per minute. But it shall be further agreed that in case (at a fair trial to be made within a stated time) the machine shall fill a scow at the rate of more than six cubic yards per minute, then \$10,000 shall be added to the price above stated for each and every such additional cubic yard thus dredged per minute, and for additional fractions of a cubic yard thus dredged in the same ratio the \$10,000 is to be added to said price above stated.

I will sell any other Territorial or State rights (either United States or Foreign) upon the same plan and at a lower price proportionately than the rights for the Pacific Coast.

I will sell a single machine with scows and all complete, and right to use the same in a limited territory, for \$30,000 on the same plan as above stated, but will add only \$2,000 to each additional yard over the six cubic yards per minute. Each machine is not to employ more than two 10x20 inch engines.

Payments to be made in U. S. gold coin on delivery of machine, as may be indicated by agreement.

Address, JOHN A. BALL,
9v28-1f Oakland.

WATER TANKS of any capacity, made entire by machinery. Material the best in use; construction not excelled. Attention, dispatch, satisfaction. Cost less than elsewhere.

ARE YOU GOING TO PAINT?

THEN USE THE BEST.

THE AVERILL CHEMICAL PAINT

WILL LAST THREE TIMES AS LONG as the best lead and oil, without OAKALING, is of any desired color. It is prepared for immediate application, requiring no Oil, Thinner or Drier, and does not spoil by standing any length of time. It is equally as good for inside as outside work; over old work as well as new; in fact, where any paint can be used the AVERILL CHEMICAL PAINT will be found superior to any other. Any one can apply it who can use a brush, which truly makes it the FARMER'S FRIEND.

IT IS JUST THE PAINT FOR THE AGE.

IT IS SOLD BY THE GALLON ONLY.

One gallon covers 20 square yards 2 coats.

For further information send for sample card and price list.

JOHN TAYLOR & CO.

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merit.

They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:

The pan being filled, the motion of the muller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Sellers made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill-men are invited to examine these pans and sellers for themselves, at the office, 229 Fremont Street, San Francisco.

They are particularly adapted to Farmers' and Minors' use. Send for Circulars and Price List to

WARNER & SILSBY,

14v28-cow-hp-3m

147 New Montgomery St., S. F.

Trouble at the Cornell Watch Factory.

The workmen at the Cornell watch factory in this city, who have been engaged for several weeks in putting up the machinery, which is now about ready for starting, became aware, a day or two since, that it was the intention of the proprietors to introduce Chinese labor into that establishment. These workmen, who have devoted several years to acquiring their trade, and who have been brought here from Chicago, on account of their especial skill in the art of watch making, fear that if they instruct the Chinese in the practice of their art, that these people will soon supplant them in the business, by virtue of their known capacity for soon becoming skillful in everything requiring light and delicate manipulation.

Moved by these considerations several meetings have been held to consider the subject and confer with Mr. Cornell, the principal proprietor, the result of which, so far, as it has transpired up to the time of our going to press leaves the matter in rather a ticklish condition for both the workmen and the company.

Out of some 70 hands it appears that only three of the foremen and eight of the men, manifest any disposition to remain. All the others proclaim it as their intention to return East, and seek employment in other factories, if Mr. Cornell continues to insist on his original intention.

This unexpected obstacle in the way of establishing a new and important industry on this coast is greatly to be regretted, and we earnestly hope that some compromise will be devised under which these newly arrived artisans can feel it to their interest to remain with us. We are not advised as to the particular class of labor to which it is proposed to assign the Chinese, but can hardly suppose it is the intention of Mr. Cornell to instruct them in anything beyond some light, simple processes, which perhaps might be advantageously turned over to some of our own girls or boys.

THE JAPANESE PERSIMMON.—This tree is beginning to attract the attention of our fruit-growers. Those who have seen the fruit in Japan pronounce it very fine, unlike anything grown in this country. General Capron, former Commissioner of Agriculture, and since for several years residing in Japan, states: "That the persimmon is the best of all the native fruits of that country, and well worthy of introduction in California." The tree is described as finely shaped, having a rich, dark green foliage, and is an ornament anywhere. It produces fruit in Japan in from six to eight years from the seed. It would not be surprising if it came into bearing earlier with us. The experiments of Messrs. Shinn & Co., nurserymen, at Niles, Alameda county, show conclusively that our soil and climate is well suited to this foreigner. They have several thousand successfully grown, large enough for orchard planting. We gladly notice any effort on the part of our culturists to introduce valuable fruit and other trees. The successful introduction of one choice variety will repay for many failures.

THE Pacific Coast Pulpit, for Dec., contains the sermon of Rev. W. H. Platt—"The Immortality of the Soul." Each volume will contain some of the most notable sermons of the year. Price \$2. Chas. F. Whitton, short-hand reporter is the managing publisher, Montgomery block, S. F.

SAGIT Valley, W. T. is looming up. The latest mineral development in that region is an extensive coal field a few miles up the river, where coal can be obtained to an unlimited extent on the surface without going to the usual expense of underground tunnelling.

New machinery for sinking the shaft of the Phil Sheridan mine deeper has been ordered. The Utah mine on the north and the Sierra Nevada on the south, both being worked deeper, keep the Phil Sheridan pretty well drained of water.

The drift run west from the shaft of the Halse & Norcross on the 2100-foot level did not disclose any solid body of ore, although the vein formation which it penetrated was of the most favorable character.

The new Quicksilver Mining company organized to work the ground of the old Welch company near Clayton, are now putting up furnaces calculated to smelt twelve tons of cinchona rock a day.

Work is progressing favorably at the Gwin mine, Calaveras county. The last sinking of one hundred feet in the main shaft is nearly completed. When done, the depth of 1,000 ft. will have been reached.

Large quantities of coal are being hauled from the Ione mines, to be used in the quartz mills at Sutter Creek and other localities.

BETWEEN 150 and 200 men are employed near the mouth of Sonoma creek in the work of reclaiming overflowed lands.

General News Items.

SHOOTING.—The emotional mania for shooting seems to be on the increase. Some woman is generally at the bottom of such trouble and not unfrequently does the shooting herself. The latest instance of such a case occurred in this city last week. A woman named Annie Smythe, shot Mr. M. G. Cobb, a lawyer of this city as he was passing along Washington street near Montgomery. The wound was at first thought to be fatal, but Mr. Cobb is now in a fair way for recovery. The woman has been arrested. The only cause assigned was a supposition on her part that he was mismanaging a land case in which she was interested, for which there was no reason whatever. It is charitably thought by many that the woman, who is a widow, was insane.

FATAL POLITICAL QUARREL.—Mr. Byerly, editor of the New Orleans Bulletin, having cast some severe reflections upon ex-Governor Warmoth, a challenge had passed, or was about to pass, when the two accidentally meeting in the street, Byerly knocked Warmoth down and jumped upon him. During the fight Warmoth drew a knife and stabbed his antagonist several times in the abdomen, from the effects of which he died the next day. Warmoth has been arrested. Byerly was a Northern man and a political opponent of Warmoth.

HAWAIIAN ANNEXATION.—Washington newspaper correspondents state that the General Government is striving to induce the King of the Hawaiian islands to use his influence for annexation. Undoubtedly annexation would be of great advantage to the Sandwich islands, and incidentally to California. The islands would also be of advantage as a way station to the nation at large.

TWO BOYS CHARGED WITH PARRICIDE.—Two sons of Jacob Nerswinder who lived 15 miles north of Columbus, Ohio, have been arrested charged with having murdered their father and then burned his body. The boys are fourteen and eighteen years old. The family deserted their house, and the remains of Mr. Nerswinder have been found among the ashes in the fire place.

P. M. S. S. INVESTIGATION.—The examination of Mr. Irwin before the Congressional Investigation Committee proceeds slowly. Mr. Irwin don't "pump" as well as it was thought he would. It has transpired, however, that large sums of the company's money went into the hands of the Congressional postmaster, but for what purpose, or where it went subsequently, has not transpired.

THE GERMAN CHURCH CONTROVERSY.—It is reported that Queen Victoria has written to Emperor William urging him to compromise the ecclesiastical conflict in Germany. The report is of doubtful authority, and Germany is generally supposed to be pretty well calculated to mind her own business, and the Catholics don't compromise worth a cent.

DROWNED.—Wm. Farmer was drowned while trying to cross the Eel river at the Fort Seward ford, on the 29th of November. He started to cross the river on horseback, and his horse failed or refused to swim, and Farmer, who could not swim, was washed from his back and drowned.

EMIGRANT SHIP BURNED.—News has been received of the burning of the English emigrant ship "Cospatrick," while on the voyage from London to New Zealand. Four hundred and sixty lives were lost. Further details are anxiously awaited. The vessel and cargo are a total loss.

CUBAN ANNEXATION.—A letter to the *Diario* reports that strong efforts are being made in Washington to obtain the recognition of Cubans as belligerents. The letter couples the names of Aldama and Collector Casey with these efforts, and says that the object is to throw on the market Cuban bonds held in Washington.

DEATHS LAST WEEK.—During the last week 79 persons died in this city, 51 males and 28 females. Of these 68 were white, 1 colored, and ten copper colored persons. There were 3 casualties, 1 homicide and 17 persons died in public institutes.

GERRITT SMITH DEAD.—This well known philanthropist died suddenly in New York on Monday last, of apoplexy. He had just arrived in that city to spend the Christmas holidays with his friends.

The great ship "Three Brothers" went to sea on Monday with 4,000 long tons of wheat in her hold. She was taken out by two tugs. This is the most magnificent specimen of naval architecture that carries sails.

HORSE BEEF.—The horse shambles of Paris supplied the public during the first quarter of the present year with nearly 630,000 pounds of meat, the result of the slaughter of 1,555 horses, mules and asses.

FATAL ACCIDENT.—Patrick Smith, foreman and section man on the California Pacific Railroad at Napa Junction, stumbled across the track on Monday morning with such force that he died almost instantly.

CALIFORNIA RIVERS.—The proposition pending before Congress to expend a small sum of money to improve California rivers ought to receive favorable consideration. But \$57,000 are required for the Sacramento River.

RAILWAY ACCIDENT IN ENGLAND.—Several persons were killed and many wounded by a railroad accident at Woodstock on Thursday last. Some of the latter are fatally wounded.

STRANGE.—The extraordinary character of the present season seems to puzzle the animal as well as the vegetable kingdom. We have already noticed the fact that the trees seem to be puzzled to know what to do, and now we find the birds equally at a loss. The *Mountain Messenger* of December 12th says: A nest of young birds was recently hatched in Judge Davidson's orchard. What does this mean? Won't some prophet investigate this unusual occurrence and tell an anxious people what sort of a winter it foreshadows?

A THOROUGHbred IMPORTING ASSOCIATION.—Articles of incorporation of the California Confederacy were filed yesterday. The purposes for which the corporation is formed are, the importation of thoroughbred horses into this State, and the improvement of the breed. The directors are George M. Pinney, Ezekiel Wilson, J. S. Taylor, A. E. Swain, John Martin, O. F. Willey and William Shear. The capital stock is \$50,000, divided into 500 shares of the value of \$100 each.

CHANGE IN THE WEATHER.—The weather during the past ten days has taken a new turn, and it is extremely cold for San Francisco; overcoats out of doors and fires within are in demand, and frost and thin coverings of ice are discernible in the morning. In Los Angeles the late severe frosts have seriously damaged the promising tobacco crop at Agricultural Park. This is the longest cold term ever known in Los Angeles. Considerable anxiety is also felt in regard to holding off the usual December rains.

Industrial Items.

THE NAVY YARD.—Eighty-two men are employed at the present time in the construction department at the navy yard, as follows: Ten men are engaged in boat building in that department. There are twenty-five blacksmiths, twenty-two ship joiners, three block makers, five spar makers, two pattern makers, seven plumbers, and eight in the saw mill.

AN INDUSTRIAL COLONY.—Westminster Colony is still on the march of improvement. Several houses are nearly completed, and were it not for the scarcity of lumber and carpenters others would at once be erected. The school is flourishing, the plows are busy, the corn crop excellent, and the number of trees to be planted this season will be greatly increased.

STEAMSHIP EXPENSES.—Some idea of the expenses attending the trial trip of a large steamship may be had when it is known that the trial trip of the "City of Peking" to Newport with a large number of guests, cost \$50,000. Delmonico's bill for the entertainment was about \$25,000.

The estimated cost of a ship canal from Stockton to Disappointment slough, eleven miles, is \$1,117,000. Such a work is greatly needed, and would be of immense benefit in opening up the San Joaquin valley.

Twenty tons of coal per day are used at the Starr mills, in Vallejo, which at present rates costs about \$130. One vessel is kept constantly running to supply fuel for this great flouring establishment. Fifteen carloads of wheat are ground every twenty-four hours.

ANOTHER WOOLEN MILL.—Active efforts are being taken to secure the erection of a woolen mill at Merced. The sum of \$32,000 has already been paid up. It is proposed to go into the manufacture of mixed fabrics—woolen and cotton.

IRON WORKS AT SANTA CLARA.—An effort is being made to get up a joint stock company at Santa Clara, with a capital of 100,000, for the purpose of obtaining the location of J. T. Walker & Co's iron works there.

The Anaheim branch of the Southern Pacific Railroad is now within seven miles of Anaheim. The track will be completed by the 1st of January.

The San Jose woolen mill company is making weekly shipments of goods to St. Louis, Chicago and Boston. The shipments of late have consisted of doeskins, cassimeres and blankets.

A NEW INDUSTRY.—One hundred and sixty acres are being planted to peppermint at Milpitas, Santa Clara county, by W. Boete.

Three hundred and fourteen men are employed at the gunpowder works near Santa Cruz.

The Sacramento beet sugarie will this year plant from 1,500 to 2,000 acres in beets.

There are eight vessels contracted to be built on Humboldt bay.

The Pacheco-road pass over the Coast range has been completed, at a cost of about \$18,000.

A company has been organized for constructing a new hall at Monterey.

SALT LAKE boasts of 200 new houses this year.

MAYOR TOREMAN, of Los Angeles, estimates the population of the city at 13,000.

The San Luis Obispo water works have been completed.

A HANDSOME hotel is being erected at Felton, Santa Cruz county.

The wharf at Wilmington is about to be extended 1,000 feet.

SINCE April 1st 29,102 immigrants have arrived overland.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington, D. C., Dec. 29th, 1874.

FOR WEEK ENDING DEC. 15TH, 1874.*

TIRE UPSETTER.—Quintus C. Tehhs, Windsor, Cal.

WINDMILL.—William C. Nelson, Sacramento, Cal.

ALARM COMBINATION LOCK.—Henry W. Dilg, Portland, Oregon.

OVERALLS.—Chesung Quan Wo, S. F., Cal.

ARTIFICIAL STONE.—Achille Berard, Oakland, Cal.

TRADEMARK.

FOR COCONUT PREPARATIONS.—The California Cocosnut Pulverizing Company, S. F., Cal.

*The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest time possible.

Agricultural Items.

FOUR CROPS OF PEARS IN ONE SEASON.—The *Foothill Tidings* of a recent date is responsible for the following: Four crops of pears from one tree in one season is one of those stories for which California is famous, but which people East seldom believe. Any one who will take the pains to walk out to near the end of Neal street in this town can satisfy himself if such things do happen. Mr. Barker has a winter Nellis pear tree in his orchard that has blossomed four separate and distinct times this year and now has upon it four crops of pears. Only the first and second crops are perfect, the others being small and immature.

ANSWERS TO QUESTIONS.—A subscriber at Anaheim asks the following questions: First, will the Muscat Alexander do well on sandy soil? Second, in what month should deciduous trees be budded? Third, what month is considered the best for planting blue gum seed?

Answers: First, yes, on "sandy soil," but not on pure sand. Second, in August and September. Third, amateurs would do well to wait until February or March before planting blue gum seed.

Of the 14,000 acres of arable land comprising Sherman island, it is estimated that 10,000 acres are already sown to wheat and barley. Several hundred acres of volunteer grain stand six inches high.

There are no new developments regarding the potato rot in Sonoma county. Nearly all not dug before the late rains are ruined. About 50,000 sacks are stored in Petaluma.

SETH BENNETT, farmer, on Dry creek, Sonoma county, gathered from one vine of Mission grapes 100 pounds of grapes, which, if made into wine would have produced eight gallons.

FRESH butter is arriving at Petaluma in considerable quantities, and is selling from 43 to 45 cents per pound, or 6 cents higher than last year.

MESQUITE grass is being sown extensively in Lake and Mendocino counties. It is said to be fine for hay, and rich green feed. Neither frost, wet, nor ordinary dry weather affects it.

When all her land is properly reclaimed, Sutter county will have added fully one half more to the amount of land now under cultivation.

SANTA CLARA county is sending more grain East this year than ever before.

The capacity of the Consolidated Tobacco factory at Gilroy is about to be doubled.

THIRTY SEVEN vessels have loaded wheat at South Vallejo this season.

A NEW ledge with very promising appearances has been found on the southwestern side of the ridge back of Pioche. The ledge is of good size, and contains ore that assays well. The owners are Murphy, Jones & Co.

The covered car track leading from the Consolidated Virginia mine to the mill of the same company is about completed. The rail for the cars is laid about half way through and the woodwork is all done.

The Calaveras Chronicle reports that the Mokelumne Hill Canal and Mining company are negotiating for the purchase of Overton's ditch, at Rich Gulch flat.

THE HOME CURE THAT NEVER FAILS.—"The atmosphere of pine woods is good for consumptive patients," says Dr. Erasmus Wilson. No doubt it is; but *Hale's Honey of Horehound and Tar*, charged with the concentrated essence of the most valuable of all medicinal trees, the Abies Balsamea, or Balsam of Gilead, and tempered with the purifying and healing juice of the horehound plant and with the purest honey, will do more in one day to cure a cough or cold than the air of pine woods could do in a twelve-month.

Pike's Tooth-Ache Drops—Cure in one minute. Woodward's Gardens embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds, and Skating Rink. Admission, 25 cents; children, 10 cents.

THE
AMERICAN TURBINE WATER WHEEL

Recently improved and submitted to thorough sci-
entific tests by James Emerson, showing the following
useful effect of the power of the water utilized, being
THE HIGHEST RESULTS EVER KNOWN.
Percentage of part gate, $\frac{1}{4}$ 50.08; $\frac{1}{2}$ 69.64; $\frac{3}{4}$ 78.73
 $\frac{1}{2}$ 82.53; $\frac{3}{4}$ 82.90. Percentage of whole gate, 83.14.
Mr. Emerson says: "These are the best average
results ever given by any Turbine Wheel
in my experience."

KNOWLES' PATENT STEAM PUMP.

It has no Cranks or Fly-Wheel, and has no dead points where it will stop, consequently it is always ready to
start without using a starting-bar, and does not require hand-work to get it past the center. Will always start
when the steam cylinder is filled with cold water of condensation.
CENTRAL PACIFIC R. R., OFFICE OF THE GEN'L MASTER MECHANIC,
SACRAMENTO Cal., January 14, 1873.
A. L. FISH, Esq., Agent of the Knowles Steam Pump—Dear Sir: In reply to your inquiry as to the merits of the
Knowles Steam Pump, in use upon this road, I will say that it gives me great pleasure to report that they have per-
formed their work well whenever called upon. In no instance have they failed. We have now over 30 of them in
use on this road as fire engines, and pumping water for shop and station use. I consider the Knowles Steam Pump the
best in use, and prefer it to any other.
Yours, truly,
A. J. STEVENS, General Master Mechanic.

A. L. FISH, Agent Knowles' Steam Pump—Dear Sir: In answer to your inquiries, we state that the highest award
for Steam Pumps at the Eighth or last Mechanics' Fair in San Francisco, was a FIRST PREMIUM and Diploma, awarded
to Knowles' Patent Steam Pump, as published in the Official List September 23d, 1871.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

[PATENTED MAY 26TH, 1874.]
Price Reduced to 16 Cents Per Pound.
SAN FRANCISCO, November 10th, 1874.
To Supts. of Quartz Mills and Mining Men generally:
We take pleasure in stating that owing to the rapid
increase in our orders, our Pittsburgh Manufacturers
have been compelled to add largely to their works—
a new gas furnace and heavier trip hammer—and are
thus enabled to reduce the cost of steel and at the
same time produce SHOES AND DIES superior to any yet
manufactured. We have consequently reduced the
price to 16 cents per pound and solicit a trial order,
guaranteeing that you will find them at least 10 per
cent cheaper than the best iron. There are no STEEL
SHOES AND DIES made excepting under our patent and
sold at this office, or by our authorized agents, though
certain Eastern manufacturers advertise STEEL SHOES
AND DIES which are only cast iron hardened by the
addition of a composition. They will not out-wear two
sets of common iron, though called steel. They are
very brittle and are not capable of being tempered,
flying from under the hammer like cast iron. Our
STEEL SHOES AND DIES are in use in many of the largest
mills on the Pacific Coast, and all who have tried them
pronounce them cheaper and far superior to iron in
every respect, even at the old price of 20 cents per
pound. Their advantages over iron are cheapness on first
cost, increased crushing capacity, time saved in chang-
ing and in setting tappets, increased value of amal-
gam by absence of iron dust and chippings, and a saving of
75 per cent. in freight. It takes 60 days to fill orders
from the manufactory East. Price 16 cents per
pound shipped at San Francisco. Terms liberal,
with dimensions, to
CASE STEEL SHOE & DIE CO., Room 1, Academy Building, S. F.

TEATS' PATENT FURNACE.

TEATS' PATENT FURNACE
For Roasting, Desulphurizing, Chloridizing
and Oxidizing Ores, etc. For the reduction of
Gold, Silver, Lead and other ores, saving a larger per-
centage, at less cost, than any other invention now in
use. Chloridizing Silver ore more thoroughly, in less
time, with less fuel, salt and labor; also roasting Lead
ore preparatory to smelting, better and cheaper than
any other invention. The Furnace is so constructed
that one man, of ordinary ability, tends five or more
furnaces; controls them with ease; adding heat or air;
stopping or starting at will; charging and discharging
with ease. Also, Patent "Conveying Cooler," for con-
veying and cooling roasted ores, heating the water for
amalgamation and the boilers at the same time. Saving
the large space in mill (covered with brick or iron),
and the labor of two men per day, exposed to the poi-
sonous chlorine gases. Also, Patent Air Blast "Dry
Kiln," for drying ores direct from the mine or breaker,
saving fuel and labor heretofore necessary in drying
ores for dry pulverizing. For description refer to
MINING AND SCIENTIFIC PRESS, No. 18, October 31, 1874.
For particulars address
TEATS & BREED,
No. 12 West Eighth Street, Cincinnati, Ohio
Circulars, &c., will be furnished, if required.

TREADWELL & CO.'S

(IMPROVED)

Upright Safety Engines and Boilers.

(MADE BY THE NEW YORK SAFETY STEAM-POWER COMPANY.)

We would call particular attention to the graceful design and simple mechanism of this Engine Boiler; the form is not only pleasing to the eye, but is, also, that which secures the greatest strength and rigidity with a given amount of material. The Boilers, which are of the Upright Tubular style, with internal fire-box, are of the highest quality. The heating surface and area of grate are in excess of the quantities usually allowed for the same power, and it is therefore unnecessary to purchase a greater rated power than is actually required, while in cases of emergency these boilers can be depended on for more than their rated power. The Engine is not fastened to or upon the boiler, and is therefore not subjected by expansion and contraction to the over-heating of the boiler, but is mounted on rollers, and is free to move in any direction. The high speed at which this Engine is necessary for economy of fuel. All parts are easily accessible—a great advantage. Is complete in itself as a Portable Engine and Boiler, or the Engine can be detached from the Boiler and run independently, if required. Its main points are simplicity, safety and smallness. It is a perfect machine, for its simplicity, small size and safe power is required in use.

All Sizes from 2 to 10 Horse-Power.

TREADWELL & CO., Sole Agents, S. F.

The above cuts represent the new style "HOADLEY" variable cut-off 15 Horse-Power Portable Engine. We have same style and size mounted on wheels as a Threshing Engine for the Russell End-shake Separator. We have all sizes from 3 to 40 horse-power on hand. The HOADLEY ENGINES need no recommendation from us. We have sold them in California for 20 years, and every year has added to their improvements. The last great improvement is the Cut-off Governor, thus giving them all the economy and increased power of the most thorough built stationary engine. Millmen, Mine-owners and Mining Superintendents, and all who intend buying engines, will do well to examine carefully the merits of the "HOADLEY" before purchasing. Circulars and prices sent free on application. Address

Iron Steam Pipe furnished with Fittings, etc. Coupling Joints of all sizes. Particular attention paid to Distillery Work. Manufacturer of "Garrett's Patent Improved Journal Metal." Highest Market Price paid for OLD BELLS, COPPER and BRASS.

Cazin's Combination Ore-Sizer and Concentrator—One Plunger System.

(Covered by Letters Patent of July 2d, 1872, and recent applications.)

Containing a sizing apparatus, (revolving screen) delivering two or four sizes of ore to two or four rows of sieves, each row independent of the other, and each having 6 sieves, each row concentrating according to specific gravity the special size automatically fed into it, resulting in the simultaneous continual delivery of separated materials, working 2d and 3d-class ores into 1st-class ores of perfect cleanness. It thoroughly separates native gold or copper from quartz or any other lode matter—galena and silver sulphurets from pyrites, baryta and quartz; and pyrites from quartz. Added to a battery of stamps these machines constitute a full system of ore concentration, sufficient in most cases for the requirements of western mines, with a capacity of 15 or 20 tons per 24 hours.

For particulars apply to,

F. CAZIN, M. & C. E.

Supt. Denver Concentration and Smelting Co.
At Denver, Colorado, Lock-Box 2225, or corner of
Blake and 32d Streets.

Thursday Noon our last forms go to press. Communications should be received a week in advance and advertisements as early in the week as possible.

GIANT POWDER.

Patented May 26, 1868.

THE ONLY SAFE BLASTING POWDER IN USE.

GIANT POWDER, NO. 1.

For hard and wet Rock, Iron, Copper, etc., and Submarine Blasting.

GIANT POWDER, NO. 2.

For medium and seamy Rock, Lime, Marble, Sulphur, Coal, Pipe Clay and Gravel Bank Blasting, Wood, etc.

Its EXCLUSIVE use saves from 30 to 60 per cent. in expenses, besides doing the work in half the time required for black powder.

The only Blasting Powder used in Europe and the Eastern States.

VOLUME XXX
Number 2.

Eastern Investors in Mines.

We received a letter this week from some people in a town in Indiana, of which the following is an extract: "We would like to have a map of the Washoe or Comstock lode; also a book or whatever is published that would enlighten a stranger on the great resources of wealth in that region. Now whatever you know to be of interest to young speculators in said mining districts please mention by mail or through your journal, so we will be able to purchase."

Probably the best thing to enlighten a stranger of the great resources of wealth of that region would be to go there and see it, or else come to the mint and look at a few cords of silver bricks. There is a great deal published which might enlighten them about the mines, but not much to enlighten them about how, and when, and where to invest so as to make money. There is considerable to tell young speculators about the Comstock, but as the advice they want probably relates to a stock that is very low and will surely go up very high after they buy into it, this question is difficult to answer, more particularly as no stock is very low just at present. The map wouldn't be of the slightest use in informing them about what they want.

Evidently our stock excitement has had time to travel across the continent, and is making some of those Eastern folks dream about large profits with little capital and no risk. But to those who are thinking of coming here to make money out of mines by investing in stocks, our advice is to remain at home. If they have made up their minds to mine, the only way to do is to come here and buy one of the many thousand mines awaiting capital for development. There are plenty of them which can be bought cheap. But if the intended immigrants have only a few hundred dollars, and expect to make a fortune out of it, they stand more chances to lose what they have than to get richer, by investing haphazard in stocks.

Mining is a business just like anything else. Anybody may stumble on a bunch of croppings and strike a ledge, but to make money out of it afterward is another thing. Deshlag in stocks is also a business, and requires much more shrewdness to be successful than many suppose. Because a man can run a plane, a lathe, or any other tool, it does not follow that he can jump at once into another man's business, and do as well as he. It needs capital to go into stocks like anything else, but a man's profits are not always proportionate to his capital.

We on this coast who know anything about mining are often provoked to laugh at the crude ideas entertained by our Atlantic brethren on the subject of mines. They hear about a man having struck a ledge which assays \$10,000 a ton. Straightway they calculate that a ton could almost fill a dumpster, and for every dumpster full they would get \$10,000. And as the ledge is three feet wide, and they can get out at least 50 tons a day, there is \$500,000 a day. When they figure up the yield for the first 30 days it gives them about \$15,000,000 on the \$10,000 per ton basis, about which time they begin to get excited on the subject. We all know what absurdity there is in figuring on \$10,000 per ton assays, or even \$1,000 per ton assays, and what they amount to, but those Eastern people hearing of our Sharone and Jones, *et. al.*, think a thousand a ton isn't so much after all.

About mining stocks they have still cruder ideas, imagining that all a man has to do is to put a few hundred dollars into a broker's hands, and in a few days it comes out thousands instead of hundreds. This is all very well in a few cases, but is not by any means the rule. The mining stock men here are quite as sharp in their peculiar business as the Wall street men in theirs, and Eastern speculators would probably do as badly here as our speculators would there. No sensible man would advise people to come here from the East to make their fortunes in stocks. There are plenty of us Californians who haven't made our fortune yet, and we want our turn first.

Hydraulic Mining in California.

No. 7.

Connection Between Tunnel and Surface.

The first opening of a hydraulic mine, as we have seen, is rather a tedious and expensive business; however, after a connection is once made between tunnel and surface, other necessary improvements are easily accomplished. For instance, the chimney represented as running up on a slope may be, if only short, changed into a vertical shaft, or, if long, into terraces, so that the gravel rushing down may be submitted to a crushing process, which a fall of 20 feet or more will create.

Where the bed rock between terminus of tunnel and basin is of considerable depth, a

very strong blow. The benefit of a drop of even a few feet on the line of sluice boxes is well known to the miner, and a repetition of such drops must necessarily cause the repetition of such benefits, which consists in the crushing, stirring up, changing of position of the "pulp," and the consequent liberation and precipitation of the gold.

By the time the tunnel is reached the force of the several falls or drops is broken, and a leap of 30 inches lodges the running mass in the sluice boxes.

Condensed from an article by Charles Waldeyer, of the last Annual Report of the U. S. Commissioner of Mining Statistics.

A COURSE OF SCIENTIFIC LECTURES.—The Trustees of the Mechanics' Institute and the University of California have arranged for a course of twelve scientific lectures to be delivered in this city. The first will be delivered Saturday evening by Dr. G. F. Becker, on the

FIG. 8. SLOPE CUT INTO TERRACES.

system of terraces will be more advisable than a vertical shaft, for the reason not only that the sloping chimney is far more easily changed into terraces than into a vertical shaft, but also that the danger of blockading or choking is greatly lessened.

The terraces ought to be constructed in such a way that the first fall is the deepest, each successive one lessening as the tunnel is approached, so that the last fall is not more than a common drop of two or three feet, such as may be found on a line of sluice boxes.

The diagram given represents a slope of 100 feet vertical height, cut into terraces.

	FEET.

The second.....	25
The third.....	20
The fourth.....	15
The fifth.....	10
The sixth and last, into the boxes.....	2 1/2
Total.....	100

Whether a vertical shaft or a slope—in other words, a single drop of 100 feet, or a succession of drops of the same aggregate depth, will be preferable, is a matter open to discussion. It seems that a succession of blows, of less force but striking the matter to be crushed from different sides, must be more effective than one

"Metallurgy of Common Metals." One lecture will be delivered on each of the following metals: Gold, silver, quicksilver, and steel. After these four are delivered, Prof. Charles E. Bessey, of the Iowa State Agricultural College, will commence a series of four lectures upon the "Useful Vegetable Products," and will be followed by Prof. Brewer, of Yale College, with a course of four lectures on coal, salt and oil. The lectures, like those heretofore delivered, will be free, but names must be enrolled with the Librarian of the Institute.

THE HOOSAC.—The Eureka Sentinel is informed that negotiations are pending in regard to the incorporation of the Hoosac Mining and Smelting company, to work the mine by that name, now the property of Harry Strout, of Eureka, who is now in San Francisco on business connected with such incorporation. The property has been developed under the supervision of Mr. Strout; the machinery, both at the mine and furnace, is in splendid working order, and should such an incorporation be made the company need not expend any money in perfecting the works, but start immediately on a working basis with a fine show of success from the start.

An eight-inch vein of cinnabar was last week found in the bedrock in the Wolf placer mine on Canon creek, Trinity county.

Academy of Sciences.

The annual meeting of the California Academy of Sciences was held on Monday evening last. No business was transacted except that of reviewing the annual reports of the officers, and the results of the election which took place on the same day.

The report of the Vice-President, enumerating the more important events of the year. The Academy has flourished, and in its new quarters, the museum is fast becoming rich in collections. Five members were lost by death during the year. The first of these was H. G. Bloomer, curator, whose library and botanical collection were purchased by the Academy. Then occurred the death of Col. Leander Ramsom and Dr. Fourgeaud, and news has arrived of the death of two corresponding members, one of them, M. Quatlet, and the other, Ferdinand Stoliczka, a distinguished paleontologist at Calcutta. The Recording Secretary, Mr. Charles G. Yale, had performed his duties with unremitting faithfulness, and in view of the very large amount of copying he has to perform, General Hewston recommended that some assistance be obtained for the mechanical part of his work. Mr. Bloomer's successor, Mr. William G. Blunt, had worked very laboriously since his appointment, in the arrangement of the museum and the library. There are now 20,000 specimens in the mineral department, principally of ores from California, Nevada and Oregon. Many of them are duplicates, and some effort should be made to exchange them for others. There are also 280 species of fishes, and 100 of reptiles, besides birds and 200 different kinds of birds' eggs in the collection. The report concluded with a pleasant reference to the generous deeds of James Lick and the distinguished services of Prof. Davidson.

Mr. R. C. Stearns presented a report on his labors as Corresponding Secretary.

The report of Mr. Charles G. Yale, Recording Secretary, contained the following: During the past year the average attendance at the meetings of the Academy has been 47 members, the highest having been 66 and the lowest 30. Eighty-three resident members have joined during the year, 12 life members and four corresponding members. Two of the resident members have become life members. Seven have resigned. Six have been dropped for non-payment of dues, and the total membership of the Academy now is 411. There are 316 resident, 75 life and 20 honorary members. Not only has there been an increase in the average attendance, but the number of papers read has been greater. During the year past there were 61 papers presented, most of which are published in the proceedings of the Academy. A list of these papers is given in the report.

Mr. Brooks' report on the financial standing of the Academy showed that on the 1st of January last year, there was a balance on hand of \$4,563.72. From monthly dues there was received \$2,961; and from life memberships, \$1,800. The total receipts were \$10,946.47; and the expenditures, \$7,988.04; leaving on hand, \$2,958.43.

Dr. Behr's report on the library stated that by the untiring labors of Mr. Blunt the volumes and papers have been neatly arranged in cases and protected from damp. There are 2,500 bound volumes and the same number of unbound.

Mr. Stearns reported that the proceedings of the Academy for the year will make a volume extending to 424 pages.

The officers elected for the ensuing year are as follows: President, George Davidson; First Vice-President, Henry Edwards; Second Vice-President, Henry Gibbons, Sr.; Recording Secretary, Charles G. Yale; Corresponding Secretary, Henry G. Hanks; Treasurer, Elisha Brooks; Librarian, Wm. J. Fieber; Director of Museum, Albert Kellogg; Trustees, David D. Colton, Geo. E. Gray, R. E. C. Stearns, Thos. P. Madden, Jno. Hewston, Jr., R. C. Harrison, W. Ashburner.

The property of the Tannehill Mining company, at Enreka, has been sold to satisfy an execution. Selden Hentzel was the purchaser, paying \$4,300.

CORRESPONDENCE.

Arizona--The Dreary Desert Trip--The Quahate Mines.

Not many years ago I listened to a glowing description of the then but little known mines in Arizona, by Christopher Carson (nephew of the celebrated "Kit"), who asserted that the then hidden and undeveloped treasures that would be found would far surpass the famed Comstock lode. Mr. Carson (who since that time was killed in a quarrel at White Pine) I thought was entitled to great consideration in his views, as being an expert in the Indian language and travelling among the Apaches almost anywhere unmolested, of course his field of observation was more extended than that of any other person. Remembering his peculiar manner of predicting the future of Arizona, and noticing the quiet drift of emigration tending that way for the last few years, and occasionally reading of some rich strike being made, my attention has been closely drawn to this southern country. So, being placed by an engagement to a large mining company, at this extreme southern town for an extended period, I shall note down from time to time the mining and other progress of this territory, for the columns of the SCIENTIFIC PRESS.

At six o'clock on the morning of the eighth of December, Gov. Safford, Lieut. Loshe and myself left the Horton House, San Diego, en route for this place, the Capital of the Territory. Our conveyance a Concord wagon, canvas top, with two seats inside and the driver's outside; drawn by four very good horses, and the redoubtable "Brown" for our driver.

What Brown?

Why, our Brown, of course. The pleasant, agreeable and noted driver, H. C. Brown--strictly temperate, always ready with a song, and, as he says, a "banking after broncos." We had a surplus of baggage aboard, the amount allowed to each passenger being only forty pounds--charges for all above that, sixty cents per pound--the fare being ninety dollars, all in greenbacks. At two o'clock we arrived at Rock Springs, 37 miles out, in Lower California--Mexico. Salt and alkali plains, with sagebrush and some mesquite. Here we had something to eat, changed horses and travelled on, through some very fair land, with fine running water, to

Hill's Ranch.

Travelled 33 miles more, and by 10 p. m. stopped a few miles from the summit of the coast range, got a good supper, changed horses and drivers--exit Brown--and in 25 minutes on we go again. What a grand mistake I made about the weather. It is piercing cold. Gov. Safford laughs at Lieut. Loshe and myself for not bringing blankets, and said we were a "verdant pair, sure enough," and wondered "why we had brought our overcoats." We managed to buy a single blanket and a pair of woolen socks, and by wrapping our feet and legs in paper and barley sacks, worried through the night. At 7 a. m. arrived at

Coyote Wells;

30 miles more! Oh how cold and sleepy. Sand dunes and rocky ribbed ledges in all directions. Got a poor breakfast, changed horses and drivers, also wagons. One of the most peculiar ideas to me is, right here in the midst of the desert where the heaviest pulling is to do, we are reduced to two horses. On we slowly go again, after an interval of 35 minutes at the worst substitute for a house I ever saw. Gov. and myself walked a few miles while Lieut. Loshe sleeps--desert everywhere, desolation supreme. Eighteen miles more brought us to

Indian Wells

at 3 p. m. Government telegraph station. Sand dunes piled upon each other in every direction seemed almost endless. Change horses, a few more miles and we are in Mexico again. At 6 p. m. we reach New river, 15 miles farther. We partook of an awful bad meal, everybody cross and another cold desert night before us. Seventy miles to Yuma. At a quarter to 11 p. m. we got to Gardiner's. Change horses, got four this time so as to make a good appearance going into town; awful dusty; get some sleep, however; roads smooth. About eight o'clock we struck the Colorado river in Mexico and wind along up its banks and we are soon back in the United States again. Castle Dome loomed up some 50 miles away where I understand some mining is being done. Arrive at Fort Yuma nine o'clock. Fort and barracks with government houses situated on the hills of the west bank of the river. Cross on a very good ferry and roll up to the hotel on a brisk trot. One long wide street dotted with one story adobe houses comprise the town of

Yuma City, Arizona.

Population, about 600. Understand no messages have been received lately from deceased soldiers for blankets. Thermometer in hotel standing at 58° at 10 a. m., calmed our surprise at the cessation of messages from Hades, not

withstanding several Indians were perambulating the town almost in nature's habiliments only. Get a good square meal and Lieut. Loshe draws on quartermaster for some of the good things of life. Procure new driver, new horses, four again to make a good show leaving town, and a small wagon or buckboard with only two seats--they call it a jerk-water. Judge it is rightly named from the many times we were jumped upon our feet and bumped around promiscuously. Gov. Safford receives congratulations of friends. Get copies of Yuma Sentinel and at 10 o'clock trot out of town and take our course along up the Gila river. Arrive at Gila city, a place of one house and a corral. At 2 p. m.; 20 miles out from Yuma city, get another square meal and roll along 24 miles more to

Fillbuster,

A stage station receiving its name from the Crabbe party who went down into Sonora some years ago to revolutionize the government and made this their last camping place before entering the State of Sonora, Mexico. Arrive at 7 p. m. and get a very objectionable meal. Change horses and proceed on to Mohawk, 22 miles; night air very uncomfortable, no sleep from the cold and rough bumping in our jerk-water. Arrive at 12 o'clock at night. Here we change horses and get a new driver, a would-be Congressman--just think of it!

The Hon. Dave Beardsley,

Late candidate for Congress from the Territory of Arizona, guide and director of our little two horse jerk-water en route for Tucson. Our sleepy heads were all awake with curiosity, and our wearied and cramped limbs straightened out, our bodies were erect with the dignity becoming the occasion for a look at the Congressional features, and a shake hands with this wonderful prodigy of the road. We were soon whirling along again after two of the sorriest "plugs" we had hitherto as yet, but the mere idea on our imaginations of the gentleman who was our driver exalted the horses into fiery, prancing steeds, each one a Bucephalus. "Tired nature's sweet restorer" overcame us for awhile, and at 4 o'clock we halted at Teamsters' Camp for breakfast--16 miles more of our wearisome journey over. The bright rays of the morning sun warmed us into life again, and we listened to Mr. Beardsley on the late Congressional canvass. He was an old friend of the Governor's, and the manner in which he described the part he took in the canvass was amusing.

"Governor, I warmed them up, didn't I, do ye see? You bet yer bottom dollar I'll make some of them hunt their holes next time by--do ye see? You can jest bet yer sweet life I'll go for them like a coyote!" Nine a. m. brought us to Stanwix station, the home of

King Wolsey

The great "greaser" hunter and Indian fighter. There are some fine lands in this portion of Arizona. The Gila bottoms are rich, and a great deal of wheat and other cereals are annually produced. Burk's station at 12 a. m., dinner, change horses and move on; the road rocky and rough; cross some high mesas or table lands; some very high hills, and pass the grave of the Oatman family, which is in a very pretty valley. The grave is neatly fenced in and on a clean white board at the head of the grave we read, "Royce Oatman and family, murdered by the Tonto Apaches, April 19, 1851. Erected by Lieut. H. L. Williamson, Troop K, 1st U. S. Cavalry, 1871." The sad details of this affair have been published in all the newspapers of the Union.

Pass the tollhouse in twelve miles more. For three or four miles from here the road runs under a rocky and precipitous bluff along the banks of the Gila, and considerable work is required each year to keep the way passable, so a certain toll is charged on all teams. On to Kenyon station, eight miles; arrive at half-past five; get a very fair meal; change horses and drivers; bid good bye to Mr. Beardsley and roll on to Gila Bend eighteen miles; arrive at 11 p. m. There we find the neatest adobe house we have come to so far, kept by a Mr. Decker. Awful cold; wrap up close and off we go for Maricopa Wells, 45 miles distant, across the worst desert we encounter in Arizona, and which, by the way, I must say is a paradise compared to the California desert. I think Arizona has been somewhat slandered, for over the road we have traveled in the Territory there has been no place but what some vegetation grew, and the interminable and desolate sand dunes of San Diego county, California, are almost forgotten in the relief we experience in traveling over the alkali plains of Arizona.

On the verge of the desert on a high plateau stands the building or buildings of the noted

Maricopa Wells,

Consisting of a series of edifices all connected with each other--hotel, postoffice, telegraph office, stage office, store, grocery, wagon and blacksmith shops, stables, corral, wagon yard and other outbuildings, all of one story adobe and belonging to a Mr. Moore, superintendent and part owner of the stage line, a very hospitable and pleasant gentleman, whose estimable wife with her kind manners and cheering conversation made us feel perfectly at home, especially the Governor, who seems to be a favorite all along the route. After partaking of a hearty breakfast, we get a new team, driver and a large wagon, and in an hour from the time we stopped we are off on the road again with one additional passenger, Mr. George H. Tyng, U. S. Marshal of Arizona. Through this gentleman I received some information about the

Silver Quahate Mines.

They lie 40 miles southeast of Maricopa Wells, in the Quahate mountains. On the Quahate claim they are down but a few feet, and have a three-foot vein of rich ore, which would all yield if worked right over \$300 per ton. Their claim lies within the 300 foot limits of the Sacaton, to which it runs nearly parallel, the ore carrying a great deal of chloride. It is now being worked by arrastras, yielding handsomely. The

Sacaton Mine

Has a shaft 12 by 12 down 64 feet in solid ore. True fissure vein 12 feet wide; 1800 pounds of ore yielded 394 ounces of silver by smelting; ores not base enough for easy smelting, but too base for easy amalgamation. The mine is now worked by arrastras, yielding over \$200 per ton. It is twelve miles to wood and water. Besides these two mines there are several other locations which have been pretty well prospected, the assays running way up in the thousands. We pass through the Pimo villages on the Gila, by the U. S. Indian agency buildings, on to the Sweetwater station 25 miles; arrive at 4 p. m. and get dinner. Here we diverge from the direct route, as the mail has to go by the way of Florence following the Gila, which makes our journey some 40 miles longer. We pass through Sacaton and arrive at

Florence

At 11 p. m., over a very good road, 33 miles. The change into a much better country is very perceptible, the land since leaving Maricopa Wells growing richer with fine grasses. Florence has as fine a fitted up store inside as any place outside of San Francisco, also fine running streams and trees growing in all directions. Change horses and drivers for the last time; get a very good supper; take on another passenger, which makes six on our wagon now, with no chance for sleep, and off we go on the homestretch for Tucson, 80 miles distant over a very fine road with a good four horse team and an excellent driver. Pass the Picacho in the night; eat breakfast at 8 a. m. at Desert station, and travel on a brisk trot by some fine ranches along the Santa Cruz river, and at 12 o'clock noon on Sunday, the 13th, after being one hundred and twenty-six hours on Concord wagons and buckboards, we arrive at Tucson, a wearied, worn out, sleepy set.

JOHN E. M.

Tucson, Dec. 18, 1874.

The Empire Mine.

The Grass Valley Union speaks as follows of the Empire mine:

This is one of the oldest quartz mines in the district, and is, we believe, the very oldest of any now being worked. The mine employs 80 miners at \$3 per day, as wages. The cost of sinking per foot is \$12; cost of drifting, per foot, \$8, and the cost of stamping, per ton, \$5. The cost of extracting ore per ton is \$8, and milling costs \$1.75 per ton. The company own the mill. The number of tons taken out and worked during the year is 11,000, and the average yield has been 16.75 per ton. The percentage of sulphurets has been 3 1/2. The total billion product has been \$187,000. The length of location is 2,800 feet; course of ledge north and south, with the dip toward the west. The length of the pay zone is 1,300 feet, with an average thickness of 15 inches. The mine is worked through a shaft which has a depth of 1,250 feet. There are 12 levels opened. Total length of drifts, 7,900. Cost of hoisting works, \$40,000. Steam power is used, and the mill has 20 stamps, which weigh 900 pounds each. Each stamp drops 72 times in a minute, and the height of the drop is nine inches. Number of pans, four; number of concentrators, ten. The cost of the mill was \$40,000, and its capacity is 40 tons for every 24 hours. The sulphurets are treated by the chlorination process.

The empire is owned by an incorporated company, whose principal place of business is at San Francisco. Mr. David Watt is Superintendent, and Mr. James Benallick is the underground foreman.

PLACERS IN NEVADA.--A gentleman who has been prospecting in Island Mountain district writes as follows to the *Elko Independent*:

I took a pick and shovel and started to work in Brown and Norton's claim at the head of the talrace, where it is about five feet to the pay ground, of which there are three feet next to the bed-rock, and out of ten buckets of this, B. washed \$5, which of course astonished me. I also went some 30 or 40 feet from this toward the side-hill and washed 10 buckets more, taking out the sum of \$2. This satisfied me beyond a doubt that the ground was exceedingly rich and would pay from \$25 to \$50 per day to the man. I spent the balance of the day in panning out, and found that two bits to the pan was a common prospect, sometimes ranging as high as \$1. I did not confine my prospects to one claim; I panned out some six or seven pans in Judd's claim, which verified the result of the other claims, and so on up to the summit of the mountain. I would just as soon have a claim of 20 acres in Hope Gulch as \$20,000 on deposit in Freeman & Co.'s bank. The miners of this place are satisfied with their claims, and don't care to sell. The water ditch is complete to the company's claims, and their hydraulic is set and ready to wash down the large bank of gravel on the bench from the creek. When they get it in full blast they will certainly take out large quantities of gold dust.

The New "C. and C. Shaft."

We yesterday visited, says the *Enterprise*, the spot where the new California and Consolidated Virginia shaft is being sunk, 1040 feet east of the present main shaft of the Consolidated Virginia Mining company. This shaft will be known as the C. and C. shaft. It is situated a short distance northwest of the works of the Virginia City gas company. We were surprised at the progress that has already been made on the shaft and at the life and bustle already visible in its vicinity. The shaft is larger than the shaft at the present Consolidated Virginia hoisting works, and is already down a distance of twenty-six feet. It is being substantially timbered from the top, and quite a strong force of carpenters is now on the ground. A small frame building now covers the shaft, but there is in process of erection over this a new building which will be 40x70 feet in size. In this new building will shortly be set up a donkey engine to be used in hoisting from the shaft. Eventually, when the shaft shall have attained a depth beyond the power of the donkey engine, there will be set up new and powerful hoisting machinery, and a new and commodious building will take the place of the temporary structure now about to be erected. Some of the carpenters are engaged in the erection of the temporary building, some in framing timbers for its interior works and others in cutting and fitting the timbers used in the shaft. Already there is enough lumber and timber of various kinds on the ground to answer as the start for a first-class lumber yard. As yet the shaft is in a gravel formation; no bed rock has been reached. The location is a fine one for such a shaft, as the ground is smooth and comparatively level in all directions about it for a great distance. Just north of the shaft is a small ravine, but this will soon be filled up to the general level with the dirt and rock hoisted from the shaft. When they begin working the great bonanza through this shaft it will be quite a lively place. In anticipation of this there has already been a considerable rise in property in the neighborhood. From \$400 to \$500 is the price now asked for lots which might have been purchased for \$100 a fortnight or two since. Already new frame buildings are to be seen going up in various directions, and the indications are that in another year or two Chinatown will again be absorbed, and that it will again be necessary to call upon the Celestials to pack their traps, pull up stakes and build themselves a new town farther out in the country; probably some where down on Six-mile canyon. In this new departure to the eastward by the California and Consolidated Virginia companies, other companies will follow at no distant day, and in a few years there will be seen numerous shafts and hoisting works extending north and south on a line with the "C. and C."

COVERED UP THE NUGGET.--The San Juan (Nevada *City*) Times says: A couple of men, one of them a sailor and the other a blacksmith, were working in a certain mine situated not far from San Juan, a few days ago, being engaged in pining against a bank of solid gravel. They were working about 30 or 40 feet distant from each other. While thus engaged, each having his eyes directed towards the bank very intently anticipating a cave, discovered at the same moment something peeping out of the bank which looked to them like a chunk of solid gold. Each dropped his pining apparatus and started toward the bank to secure the prize, but before they reached it a cave came and covered up their treasure. The adage of the fox and the grapes will apply to the incident. The fellows are working like Trojans night and day to unearth the chunk of gold.

BEAVER DISTRICT.--A correspondent of the Salt Lake *Tribune* says: Joseph Smith and others have made arrangements to immediately erect a thirty-ton furnace at a large spring, near Minersville, where an abundance of ores can be obtained to keep it going. The cry is sent us a railroad to haul the bullion away, and this ores too, for in the range adjoining Lincoln district has been found large quantities of milling ore, which, as soon as a railroad makes its appearance, will be shipped forthwith, to some good and reliable mill or mint, there to be crushed into trade dollars. The whole mining interests in and near Beaver, and for 50 miles around, are looking up. Every day I hear good news from the miners in Star. Beaver Lake District will also shortly be placed on the list as good, and now is the time to invest.

THE Eagle mill started up last Thursday, says the *Silver State*, and the machinery ran smooth as oil. The capacity of the mill is 18 tons per day. A drift is being run on the ledge from the bottom of the shaft 130 feet from the surface. Two shifts are employed in sinking the shaft and two more in running the drift, which is now in 60 feet from the shaft. The ledge is from three to four feet wide the whole length of the drift.

VILLAGE BELLE.--The Village Belle in Unionville continues to excite the good people of that town. The ledge is located on a steep hillside, and a tunnel has been run on the ledge 50 feet into the hill. A cross drift from the end of the tunnel 24 feet long has not reached the foot wall. This 24 feet is in vein matter, principally decomposed quartz, all of which assays well in gold and silver.--*Silver State*.

MECHANICAL PROGRESS.

Economic Use of Fuel.

The following interesting summary is from an address recently delivered before the Royal School of Mines, at Berlin, by G. F. Becker: The progress in the economical consumption of fuel in the last fifty years has been enormous, and has been effected in great part by metallurgists; and here again we find the scientific men taking the lead. In the economical application of the heat developed by fuel, the Bessemer process is enormously effective, not more than ten pounds of coal being requisite for the production of a hundred weight of steel from pig iron by this method, while in the older process, still in use for fine qualities of steel, two hundred and fifty pounds are needed. Siemens, by making the heat which would escape through the chimney of an ordinary furnace warm the fuel and the air necessary to combustion, obtains an economy of two-thirds the weight of fuel. It was Faber du Faur, an accomplished Bavarian metallurgist, who first made practical use of the gases which formerly escaped in immense quantities from the tops of blast furnaces and the enormous blast engines, the hoisting engines, pumps and hot blast stoves, even the roasting kilns of such establishments now-a-days require no fuel except this long-neglected waste product. Bischof, another German engineer and metallurgical author was the first to produce gas artificially for smelting purposes, and this was certainly one of the greatest advances ever made in our art. By first turning it into gas, fuel can be much more perfectly consumed than in the solid form, and hence can be made to give us, as in the Siemens furnace, in which only gas is used, a much higher temperature than is practically attained by the combustion of coal in the ordinary way, but perhaps the greatest advantage of gas is that substances, in general scarcely regarded as fuel at all, can be employed for the production of gas with the most brilliant results, a matter of the greatest importance, especially in a region destitute of true coal, like California. Lindius, a noted and thoroughly educated Swedish metallurgist, has taught us how to produce gas from wet sawdust, entirely without preparation, of such power that wrought iron may be melted with it, and the great difficulty is to find any material infusible enough to answer as a lining in the furnaces where it is consumed. You will receive some idea of the importance of these improvements from the fact that the economy in fuel effected in England alone in the year 1872, as compared with 1871, by the progress made in the introduction of more perfect apparatus, represented more than four millions of tons of coal.

Glass For Veneering, Paneling, Etc.

Attention has already been made in these columns to the use of glass for lining of tanks, etc., and to take the place of the ordinary enamel on iron—a method for the practical accomplishment of which has been devised and patented. The great object to be gained by this is a surface easily cleaned, and the possibility of perfect cleanliness—as for fermenting vats, etc. It also offers a solution to the lead poisoning difficulty. It may also be used for veneering and decorating purposes, in many cases with very good effect. Designs might be colored and placed under glass and so preserved from fading and wearing. Another good suggestion has been made by a writer in the London Builder that thick glass might be easily and cheaply cemented to the walls of hospitals, etc. It would be non-absorbent, imperishable, easily cleaned, readily repaired if damaged by accident, and, unlike paper and paint, would always be as good as at first. Glass can be cut or bent to conform to any required shape. If desired, the plates may be colored any cheerful tint. The non-absorbent quality is the most important for hospitals and prisons, and, we should think, is worthy the consideration of architects. NEW ENGRAVING PROCESS.—M. de la Grys reports a new process in engraving on copper. It consists, says the Scientific American, in first covering the plate with a thin coating of adherent silver, which is in turn covered with colored varnish. The lines are then drawn with a sharp point, after the fashion of using a diamond for stone engraving, and subsequently sunk into the plate by means of the action of perchloride of iron. IMITATION PATENTS.—The practice of patenting imitations of articles of standard excellence is growing in favor in the United States. A patent lately granted is for producing an imitation of Russian sheet iron. This is done by hammering the sheet between anvils and hammers that have indented surfaces, so as to give the sheet a mottled appearance. Another patent is for an imitation Swiss window shade, in which the lace work is imitated by stencils. IMPROVING RIVER NAVIGATION.—An appropriation was granted by the last Congress, furnishing \$40,000 for improving the navigation of the Ohio, near Pittsburg. It is expected that this appropriation will test the efficiency of the system of the improvement of rivers by the erection of dams.

Cutting Steel Rails Cold.

The cutting of a file in halves with soft iron is an old lecture experiment. The soft iron forms a disc about six inches in diameter, is mounted on a lathe spindle, and run at about 2,000 revolutions per minute. A file held to the edge of the disc is cut in two in about ten or fifteen seconds, the disc being unharmed. The shower of sparks renders this a brilliant experiment, very popular with a general audience. The principle involved is now being applied for a practical purpose. Mr. Charles White, manager, Sir J. Brown & Co.'s Works, Sheffield, England, has found the cost of cutting off the ends of steel rails cold in the ordinary way so enormous that he resolved to try another experiment. For experiment, he had an ordinary rail saw put in the lathe and all the teeth cut off. The revolving disc was then mounted on a spindle and driven at nearly 3,000 revolutions a minute. This disc was 3 feet in diameter, so that its circumferential velocity was about 27,000 feet, or over five miles a minute, or over 800 miles an hour. Steel rails forced against the edge of this disc were easily cut through in three or four minutes each. The rails weighed 65 pounds to the yard. Sparks flew in abundance, and the disc appeared to melt the rail before it; but after cutting five rails the disc itself was not sensibly warmed. The experiment was such a complete success that the firm intend putting up a very powerful saw for the purpose of cutting cold steel rails.—Ironmonger. Saws of this kind and for the purposes similar to those named were in operation at two steel works in Pittsburg, Pa., before the experiments at Sheffield were made public. The application is no doubt a very important and valuable one. BRONZES INCRUSTED.—This is the name given to a new style of bronze or copper work ornamented with gold and silver and manufactured in Paris. The ornamentation is produced by etching and electroplating, and consists in the following operations: After the object which may be of massive copper or bronze, has received the desired form; the drawings are made with water colors, the body of which is white lead. If several pieces are to have the same design, it may be printed on as in porcelain and faience painting. Those portions of the surface not painted are covered with varnish. The article is then placed in dilute nitric acid where the paint is dissolved off and the surface of the metal is etched to a certain depth. When the etching is finished the article is washed with water and immediately placed in a silver or gold bath, and a layer of the precious metal deposited by electricity on the exposed portions. When the latter operation is finished the varnish is perfectly removed and the whole surface ground or polished so that the ornamental portion is just even with the remainder of the surface. The contours are quite sharp. The surface is then bronzed which does not change the color of the gold or silver. A specially fine effect is obtained by producing a black bronze of sulphuretted copper on portions of the surface between the silver ornaments. A copper vessel then has three colors, black and white drawings on a red brown ground of snoboxide of copper. This new process for ornamenting metals has been devised at Christoffe's works since the Paris exposition of 1867. These goods are so expensive as to be only accessible to the few, although much cheaper than those in which the engraving is done by hand, and the gold or silver inserted by mechanical means. The production of an incrustation requires a high degree of manual skill and patience, but no costly machinery. Every brass foundry contains all the necessary tools for the mechanical operations. A NEW SHELL.—Various experiments have been made by a War Committee on explosives, with a view of ascertaining the practical effect of Professor Abel's proposed plan for the bursting of common shells filled with water, by means of a detonator, consisting of dry compressed-gun-cotton enveloping a small cap of fulminate of mercury. Some months ago the practicability of exploding 16-lb common shells in this manner was satisfactorily established, and the result of such an arrangement was the bursting of a shell into 300 fragments, whereas only about thirty pieces were produced by the explosion of an ordinary bursting charge of gunpowder. The effect of such an explosion among troops in the field could not be otherwise than disastrous in the extreme. Lately, however, experiments have been made with 9-inch common shells, which far exceed in effect that of any conducted with the field service common shell. On this occasion the bursting element employed was wet gun-cotton in lieu of water. The result was extraordinary, the shells bursting literally into thousands of pieces. IMPROVEMENT IN MAP MAKING.—Lloyd, the famous map man, who made all the maps for General Grant and the Union army, has invented a way of getting a relief plate from steel so as to print a map 40x50 inches in size on a fast working power press. This will so much cheapen the price of map-making as to enable him to furnish an unmounted map of the above size on bank note paper, plain and unvarnished for 10 cents, or 25 cents colored and varnished.

SCIENTIFIC PROGRESS.

The Vacuum an Absolute Non-Conductor of Electricity.

We condense the following from the Scientific American: "The passage of electricity through rarefied air constitutes a well known experiment in the lecture room of physical science. The oldest style of performing it is to attach, by means of a stop-cock connection, a long glass tube to the air pump, each end of the tube being provided with brass caps. The electricity may be made to flow through its interior as soon as the exhaustion of the air has proceeded to a certain extent; then a most beautiful exhibition is produced in the dark, resembling the aurora borealis; hence such a tube is called an aurora tube, and the aurora borealis has been ascribed to a discharge of electricity from the polar regions to the equator, through the stratum of rarefied air above the clouds. Experiments prove that electricity is retained on the surface of bodies by the presence of the atmosphere, which is an isolating substance; and that when its pressure decreases, the escape of electricity becomes easier; while, in a good vacuum, the resistance to escape becomes zero, and the electricity flows off and cannot be retained at all. This has for a long time been the accepted theory, and is still taught in most text books on physics, and is believed in by most electricians; but that it is an error was proved by Becquerel, Hawksbee, Gray and Snow Harris, as they showed that even the weakest electric discharges could be retained in vacuo. Becquerel even went so far as to show that the charge was retained for 15 days, provided that the vacuum was so perfect as to be equal to a mercurial pressure of the twenty-fifth part of an inch; and he concluded that, in a perfect vacuum, the body would retain the charge for ever; in other words that electricity could not be transmitted through an absolute vacuum. Du Moncel, in his lately published French work on the Ruhmkorff coil, gives an account of his experiments in passing a powerful electric current through a tube in which the air was being more and more rarefied, and states that, when the vacuum was made very nearly perfect by the continued operation of a good air pump, the passage of electricity through the tube continually diminished; so that at last, when the pressure had decreased to less than a half millimeter (one-fiftieth of an inch) the light had almost disappeared, while tests proved that very little electricity passed; when, however, a little air was gradually admitted into the tube, the electric current was re-established, and the light appeared again. Gassiot was the first who attempted to make an absolute vacuum, deprived of all traces of air or gas. He produced a vacuum much more perfect than any one ever did before; while his manner of procedure allowed the experiment to be extended over several days, and even weeks. When the vacuum had been made with the air pump on carbonic acid, an electric discharge, which, in the air, would not pass over a distance of half an inch, traversed 20 inches with the greatest ease. In proportion as the vacuum became more perfect by the absorption of the carbonic acid, the discharge tended to fill the tube with a more and more pale luminous vapor. The vacuum becoming more perfect in the course of several days, the luminosity became confined to the sides, where the platinum wire, which conducted the electricity, entered into the vacuum; and a certain space, half way, became dark, and this darkness extended itself, so that, in a tube of 20 inches length, it occupied nearly 10 inches. When a galvanometer was placed in the circuit, it indicated that there was no longer a constant discharge as before, but occasionally alternate discharges; when also the tube showed light flashes, and the so-called stratification of the light. When at last the absorption went on, and formed a perfect vacuum, perfect darkness was obtained in the tube, and no trace of light showed itself, even with strong electric charges, while neither the galvanometer nor an ordinary vacuum tube, when introduced into the circuit, would manifest a trace of any current. From all this, it is therefore evident that it is practically demonstrated that the absolute vacuum is not only a non-conductor, but that it is absolutely impenetrable by electric discharges. SINGULAR CAUSE OF BOILER EXPLOSION.—The tube of a boiler recently exploded in a foundry at Liege, Belgium, was caused, as shown on examination by the corrosive action of ferrous sulphate and sulphuric acid, derived from the sulphur in the coal fuel. This discovery strangely points to the necessity of carefully and frequently cleaning the forward portion of the boiler tubes, and other parts which do not come in direct contact with the flame. THE MAGIC LANTERN IN DISEASE.—Dr. Balmano, a London surgeon, has successfully applied the magic lantern to the study of diseases of the skin. A transparent photograph of the skin is taken and then placed in a magic lantern. A strong hydro-oxygen light casts the picture enlarged on a white sheet, and in this way the smallest details are brought out with astonishing minuteness.

The Mysteries of the Human Throat.

Dr. Frederick Fieber, of Vienna, like the little boy with his drum, not content with enjoying the melody of Madame Pauline Lucca, has made a close scrutiny of the throat whence the sweet sounds issue, and publishes the result of his investigations. The mechanical apparatus which is the instrument of the mental faculty, appears, in Madame Lucca's case, to be beautifully perfect, the result to some extent, perhaps of congenital fitness, but also doubtless, partly of the scientific training to which the artist has been subjected in early youth. Examined under the laryngoscope, the larynx appears small and well shaped, its several parts being marvelously developed and perfect. The true strings are pure snow white and possess none of the bluish tinge common among women. Although shorter than usual among vocalists they are stronger in proportion and amply provided with muscle. When at rest they are partially screened by the false strings; but Dr. Fieber, who watched Madame Lucca's throat through his instrument whilst she was singing, noticed that as soon as a tone was struck, they displayed themselves in their full breadth and strength. The aid given by a suitable form of mouth to the production of vocal music is a novel and interesting point brought out by Dr. Fieber. On being admitted to a view of the artist's mouth he was at once struck with the spaciousness and symmetry of its hollow, the otherwise perfect symmetry being impaired only by the absence of a tonsil, which had been removed, as well as with the vigor with which every tone produced raised the "sail" of the palate. Dr. Fieber is of opinion that the natural conformation of her mouth accounts in a large measure for the wonderful power Madame Lucca possesses of raising and dropping her voice alternately. The sound waves are naturally strengthened in so favorably shaped a space, while the muscles of the palate appeared to have acquired exceptional strength and pliability by long practice. METALLIC SULPHIDES.—The reactions of sulphuretted hydrogen upon metallic salts are very different and often much opposed, according to the nature of the bases of the acids, and finally of the concentration of the solutions. Sulphuretted hydrogen precipitates weak solutions of lead, of copper, of mercury and silver; and this precipitation so often utilized in analysis is always accompanied by a disengagement of heat. A number of experiments show that a solution of sulphuretted hydrogen changes the chloride of silver and the bromide of silver into the sulphides. It has also been proved that the contrary reactions can be realized. In other terms the sulphuretted hydrogen decomposes the chlorides of lead, of copper, and of mercury in weak solutions, whilst hydrochloric acid ought to decompose in an inverse sense the corresponding sulphides. It is the decomposing action of the water upon the neutral salt which is the origin of the observed absorption of heat. Sulphuretted hydrogen ought not, in principle, to decompose any salt of manganese. However, sulphuretted hydrogen attacks, in truth the acetate of manganese, with a sensible precipitation of sulphide of manganese and also with the absorption of heat. ACTION OF MAGNETS ON SPECTRA.—An important fact has been noticed by M. Choquet of the French Academy of Sciences, which may seriously interfere with many of the conclusions heretofore drawn from the appearance of the spectra of the heavenly bodies. M. Choquet states that the effect of magnetic influence on the spectra of the flames of sulphur and selenium is to cause them to pale and finally to become quite extinguished. On the other hand the same influence multiplies the rays and renders more brilliant the spectra of chlorine and bromine. The effect, says the Investigator, is so rapid as to seem magical. The result of these discoveries is to render the deductions from the spectra of the heavenly bodies only to be accepted with great caution, as they virtually introduce a new element to be considered in drawing conclusions from the aspect of the same. AN EXPERIMENT WITH SILVER.—Böttger offers the following experiment to show the formation of binoxide of silver and metallic silver by electrolysis. A concentrated solution of nitrate of silver is placed in a wide glass cylinder, and two platinum wires, forming the poles of a galvanic battery, are placed in the solution in a vertical position, about three inches apart. Beneath the anode is placed a small watch glass, and the current from two Bunsen cells started. In a few minutes brilliant needles of binoxide of silver appear on the anode, and becoming too heavy to remain unsupported, fall on the watch glass beneath. On the cathode an equivalent quantity of pure metallic silver collects in snow-white dendritic ramifications. FATTY MATTERS IN CAST IRON.—An experiment made long ago by Froust revealed the fact that fatty matters can be extracted from cast iron when the latter is dissolved in certain acids. M. Cloez has recently separated these materials in a pure state, and their analysis reveals the interesting fact that they consist of carburets of hydrogen of the series C²nH²n, and present all the terms thereof at least from C⁸H¹⁶—propylene—to C¹⁶H³². This is a veritable organic synthesis, realized by the aid of substances purely mineral, and is susceptible consequently of important applications. In the Science Record for 1873 will be found an account of the extraction of similar matters from meteoric iron.

Mining Stocks.

Mining stocks continue "booming." The whole town seems in a state of excitement and nothing is heard but ore, drifts, levels, bonanza and other mining terms. Everybody talks stocks, and reads stocks, and there seems to be no other topic of interest at present. Cash sales are the rule, and the margin buyers have taken a back seat or are content with fewer shares and smaller profits. Our stock table in this column show the prices of all the stocks, some of which are almost fabulous, compared to their value a year since. The great bonanza on the Comstock is the talk of the country or city, and is said to be still spreading to the eastward. Prospecting has been stimulated around the Comstock to a great degree, and claims are being located on the mineral belt in all directions. The *Enterprise* says: In all directions along the Comstock and in the silver belt the utmost activity prevails. Not only is work being most vigorously prosecuted on the old claims, but much work is beginning to be done on new locations. It has now come to be the pretty generally received opinion—the suggestion was made by us a short time since—and that a certain belt of country is silver-bearing that it makes but little difference whether or not quartz is found on the surface so long as the location is favorable and the rock shows certain characteristics. This metalliferous belt is pretty strongly marked on the surface—the hills and the ground being of a yellowish or reddish tinge, very different from the dead hue seen in hills where the underlying rock is pure granite or other barren country rock. Below Gold Hill all the prospecting companies are very active, and all have new ideas of the strength and capacity of our silver range. When day after day they are driving ahead in the Consolidated Virginia without passing through their ore body the most experienced miners, experts, scientists, and all who know anything whatever of ores and mines are astounded. At once their ideas of the value of a location anywhere within the mineral belt go up at least one hundred per cent., and they do not feel like calling any mine "wildcat." Three months hence the mining excitement will not be confined so exclusively to the north end of the lead as it is at present. There will be developments made that will cause it to spread to the southward.

THE Moore & Morgan, on the Comstock, is a newly located mine, situated at the head of Comstock ravine, near the Enropa mine, and some five thousand ft south of the Consolidated Virginia. The croppings at the surface look very favorable, and as if it would not require any great depth to find pay ore at that point. The locators are energetic men, with plenty of capital.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's Office, San Francisco.

NORTH-WESTERN QUICKSILVER M. CO., JAN. 4.—Location: Sonoma county. Capital stock, \$1,000,000. Directors—John Garber, David McClure, W. H. Sears, Israel K. K. and Wm. A. Stuart.

COEAN-VIEW QUICKSILVER M. CO., JAN. 6.—Location: San Simeon Mining District, San Luis Obispo County. Capital stock, \$6,000,000. Directors—H. K. Moore, J. H. Dall, E. B. Burdick, J. F. Greenman and Daniel

The following named companies have filed certificates of incorporation in the office of the Secretary of State at Sacramento:

ELK GROVE COAL CO.—Capital stock, \$1,000,000, in shares of \$10 each.

ELK GROVE BUILDING CO.—Capital stock, \$3,000, in shares of \$5 each.

INCREASE OF CAPITAL STOCK.—The Virginia Consolidated M. Co. has filed a certificate of increase of capital stock with the County Clerk. The capital stock has been increased from \$3,000,000, divided into 30,000 shares of \$100 each, to \$5,000,000, divided into 50,000 shares of the par value of \$100 each. The certificate states that \$5,000 of the capital stock has been paid up on the total amount of debts of the corporation is \$1,000, secured by the mining ground and property of the company; that the owners of more than two-thirds of all the shares of the company voted in favor of increasing the stock.

THE BLACK HILLS.—A letter from General Custer at Fort Abraham Lincoln, Dakota, sharply assails the statement made by the Indian Commissioner, in his annual report, or stating that there was no indications of mineral, etc., in the Black Hills, Custer asserts that the dispatches of the correspondents and explorers on the subject, are accurate; and also his own official dispatches, General Sheridan's annual report, Professor Winchell's report and various others. He imputes to the Commissioner either ignorance or failing less excusable, for his statement on the subject.

In the Chollar-Potosi mine no encouraging developments being found in the prospecting at the fifth level, work at that point is discontinued. The 1100-ft level is being pushed forward in good style and vigorous and thorough prospecting will be done at that point.

THE new hoisting worke of the Woodville mine, on the Comstock, have started up and operate splendidly. The new shaft will now be put down with energy and dispatch, the new hoisting worke being just what was needed.

MINING SUMMARY.

THE following is mostly condensed from journals published in the Interior, in proximity to the mine mentioned.

California

CALAVERAS COUNTY.

RICH STRIKE.—Calaveras Citizen, Jan. 2: During last week rich strikes were made in claims near Altaville by Cogswell & Neezer, and also by William Hale. Mr. H. has been engaged for the past four years prospecting in the claim where his efforts have at last been crowned with success.

STRUCK IT.—Calaveras *Chronicle*, Jan. 2: We hear that gravel has been struck in the claim belonging to Judge Shear, located near Central hill. The workmen are in close proximity to the blue lead.

WEST POINT DISTRICT.—A rich strike was made in the 90 ft south level of the Mina Rica last Monday night. The ore shows free gold plentifully, and measured, then, four feet in width. The Jos-phine, also, shows four feet of milling ore, a small portion of which is high grade. Henry & Son, who bought the old Thome mill, have nearly completed repairs. They intend to overhaul the mill in the spring and add first-class improvements. They have sufficient ore in sight, in their mine on Valentine hill, to keep the mill at work all winter. Recently, while work was being done on the Bartolo to comply with the U. S. mining laws a new and healthy body of ore was discovered near the surface.

SHEEP RANCH.—The Wallace & Ferguson mine is situated right in the centre of the town, and is worked through a tunnel some 1500 ft in length. At equal distances along the line of the tunnel three shafts have been sunk, two of which are at present used as hoisting shafts; the bottom of the lowest being the motive power. The depth of the lower shaft is 93 ft; of the upper, 115 ft. The vein varies in width from one to two feet, the ore paying from \$50 to \$300 per ton, and runs through the entire thickness of the lead. The company owns a 5-stamp mill, in conjunction with Mr. W. I. Armstrong, which is kept running night and day on rock from the mine. The Wallace & Ferguson is the only mine working in the district at present, if I except the Lodi, which Messrs. Hull and Fisher have just started to re-open. The Lodi formerly paid fair dividends, and the gentlemen are very sanguine of good results in the future.

CONTRA COSTA COUNTY.

THE QUICKSILVER MINE.—Countra Costa Gazette, Jan. 2: Since mention of the progress of operations by the new company on the old Welch quicksilver claim, some four or five miles south-east of Clayton, in our issue of last week, we have had a chance interview with Mr. Ryan, the superintendent of the new company, who informs us that the company is composed of persons who have had sufficient mining experience to enable them to form a fair judgment of their chances of success in the undertaking, and to enable them to endure the disappointment should it prove a failure; which, from present favorable indications they do not expect. They have expended about \$10,000 up to the present time, and expect to have their furnaces completed and ready for smelting by the latter part of February. They are running two tunnels for the cinnabar deposit, the upper one of which is now in 100 ft., and has a little more than 200 feet to go, on the calculation made, before striking the ore mass for which it is running. The lower tunnel they calculate will touch the ore depo it 300 ft below the surface, and will run 500 ft to reach it. They have already gathered ready for the furnace, several hundred tons of rock, a portion of which is of low grade but contains quicksilver in sufficient quantity to pay for smelting, while much of the rock is very rich, and he calculates that it will altogether yield very handsomely, though gathered from or near the surface. Mr. Ryan seems a very candid man of good judgment, and he appears very well satisfied that the company have a good prospect.

NEW HOISTING WORKS ENGINE HOUSE.—In

place of the engine house at the new shaft of the Black Diamond Coal company, that was destroyed by an incendiary fire some eight or ten weeks ago, a fine brick building has been erected and is now completed. The damaged engine and hoisting drums have been repaired or replaced with new work, and it is expected that the machinery will soon be put in operation and employed in raising coal through the new shaft. The company have also put up a new brick building for use as an office at the mines.

INYO COUNTY.

PANAMINT IRON.—Panamint News, Dec. 29. The shaft upon the Wyoming mine is down nearly 35 feet (below the graded level, which would add 20 feet more), and shows high grade ore nearly the whole size of the shaft. We also have it from good authority that all the mine on that side of the canyon are either improving or bolding their own at every foot sunk.

New Coso.—Wm. T., better known as Bill Grant came in from New Coso a couple of days since, and informs us that several new and, apparently, valuable locations have been made there in the last few days. Among others, one is due by J. B. Hughes, Martin Mee and the fore-said W. T. Grant, which displays a great amount of carbonate, running by actual assay as follows: silver, 59 ounces per ton; lead 50

per cent. Armstrong and Carroll, of this place, have also made a promising location. Billy Goodwin, in the interest of Belshaw & Co., of Cerro Gordo, was in camp, taking a view of things.

LABOA IN PANAMINT.—The question "is the labor demand in Panamint fully supplied?" may be safely answered in the affirmative; but the time is near at hand, we conscientiously believe, when at least five times as many persons as we now have can find profitable employment. It should be borne in mind that but a few months ago Panamint could be approached only upon the backs of animals and then with the greatest difficulty. The wonder is that not so little but that so much has been done, and that so many hundreds now find profitable employment where then a bare half dozen lonely prospectors sat over their camp-fires and held grim counsel as to when, where and how their next supply of the sheer necessities of life were to be obtained and paid for—millions under their feet but not a cent in their pockets! Where, we ask, is there another silver mining district on the coast which in such a very brief period since it was a "howling, almost inaccessible wilderness," can, or ever did, make such an actual, substantial display of wealth, population and permanency as this, or make a greater return in silver bullion for the work done when we consider all the circumstances—the shortness of time and lack of nearly every requisite for successful mining or even a comfortable existence? We consider Panamint without a parallel in actual progress and solid merit—and but a line of its great history is yet written.

KERN COUNTY.

The railroad at this time would have been completed and in running order to a point 21 miles in advance of the Bakersfield depot but for want of iron. This is now going forward. Eight truck loads went forward Tuesday, and we learn that several lots have passed since, so that but little time will elapse before the rails will be laid the distance referred to. No permanent stopping place, however, will be made there—only such temporary arrangements as may be necessary for the accommodation of the Inyo trade. The permanent depot will be three miles further on. Intervening some deep cuts are to be made. This will be mainly for the accommodation of Havilah, Kernville, the South Fork and the contiguous mining region. About 20 miles more will bring the road to the summit of Tehachapi, after which, if it is deemed advisable to tap the great mining region beyond more effectually, there are only the difficulties of a nearly level plain to contend with. The great bar to its development has hitherto been the necessity of freighting by way of Los Angeles, and it is a terrible incubus now. This will be removed in a few weeks and the mines made of comparatively easy access, and within a year they will be just as accessible, as soon as the road surmounts the summit, as any part of the State. The good time coming is eagerly looked for by the people of Kern and Inyo counties.

LAKE COUNTY.

SILVER DISCOVERIES.—*Bee*, Jan. 2: Last week William Williams discovered a ledge of silver-bearing rock in the vicinity of the Highland springs. On last Tuesday a ledge, supposed to be of the same character, was discovered in Scott's valley. The parties have sent samples of the rock to San Francisco, for assay.

GOLD QUARTZ DISCOVERY.—James Tyler, of Tyler's ranch, about midway between Lakeport and Cloverdale, has discovered a well defined ledge of gold-bearing quartz, on the ridge that divides the waters of Russian river and Clear lake.

MARIPOSA COUNTY.

CATHAY VALLEY.—*Cor. Mariposa Gazette*, Jan. 2: Cathay's valley is destined to be one of the richest mining districts in the State. There are within the bounds of the valley, 12 quartz veins that we know prospect in free gold all the way from six dollars to 80 dollars per ton on different veins. Our outlook is very flattering. Mr. Williams, of the Francis mine, is talking of building a new quartz mill below the Francis mine, of a capacity that will crush all the custom quartz that may be taken to his mill. When Mr. Williams talks he means business. There is a fair prospect of a quartz mill being built in the upper end of the valley the coming spring or summer, as the present necessity requires it. A full supply of quartz will be furnished to any company that will first put up a mill in the upper end of the valley and make fair returns of what the quartz contains. The whole valley is a perfect network of quartz veins, and many of them have hidden pay shutouts on them that will fully pay the prospectors for hunting them.

NAPA COUNTY.

NEW DISCOVERY.—*St. Helena Star*, Dec. 31: We are informed that Dr. Michel, Mr. J. J. Dickenson, and Mr. Swarts, of Pope valley, have located another lode of fine chrome iron eight miles from Calistoga, on the route of the road from that place to the Phoenix mine. We have a specimen of it now in our office which will go over fifty per cent. chrome. The same company are working a ledge of chrome iron, about eight miles from here, in Mowe's canyon.

The silver mine discovered by Chapman & Co. is prospecting well, and ore is being taken out which assays from \$20 to \$80 a ton. In the immediate vicinity of the town two more claims are being worked for silver ore, and the indications are exceedingly favorable.

TUNNELING.—The *Olistoga Free Press* notes:

The owner of the Emma mine, Jacob Cook, is running a tunnel into the hill, and has struck some very rich ore. This mine is situated about two miles, northeast of Calistoga, and the ore thus far brought to the surface evidences a large amount of wealth, which only needs time and labor to secure abundant riches for the owner.

NEVADA COUNTY.

OMAHA MINE.—*Grass Valley Union*, Jan. 3: On the first day of this month and the first day of the year, the Omaha struck into extra good ore. The rock was rich enough to justify the employment of a reliable guard over the dump pile. A man could very easily put thirty or forty dollars from that dump pile into his vest pocket. We intended last evening to go down and glean but we heard that McFate and a shot-gun were on guard, and then we concluded that to walk two or three miles on a dark night is no healthy exercise.

EMPIRE MINE BRICKS.—The Empire mine sent a couple of gold bricks below on New Year's day, a gift to the stockholders, and the bricks aggregated in value the amount of about \$21,000. The Empire, underground, is daily improving in appearance. It is one of the oldest mines in the district and has bottom as well as a good degree of speed.

YESTERDAY was pay day for the Idaho mine. The miners found the money ready for them at Findley's bank. The Idaho pays off every month quite a little army of men—good men at that.

The Darmonth mill started up yesterday morning and was stamping gold out of cement at last accounts. The mine is yielding plenty of the cement to keep the mill constantly going.

THE MINING SITUATION.—The Grass Valley mines have done well during the past month, and some of them make a good showing for the year. There are, however, too many idle mines in the district—mines that only await drills and picks and gads and powder, and other appliances, including pluck and muscle to cause them to show the "bonanza." During the month just passed a great improvement over the month before has been shown here, and that was because more work was done, in a prospecting way last month than in November. There is no doubt but that when work is done in this district pay is sure to follow. That has proved true more than a thousand times.

SANTA CLARA COUNTY.

ALMADEN.—*San Jose Mercury* December 31: The New Almaden Quicksilver Mining Company has been making some extensive improvements at Hacienda. A new smelting furnace of new manufacture and entirely different from anything else of the kind now in use in the United States, has been put up and arrangements are now being made for the erection of still another of the same kind. The old furnaces will not be discarded but will be kept in use and worked to their fullest capacity. New and large condensers are also being constructed, and such other works as are needed for the development of the mine. The company gives employment to a young army of men.

SISKIYOU COUNTY.

SCOTT RIVER DITCH.—*Yreka Union*, Dec. 30: We learn that Joh Garretson has surveyed and located a mile and a half or two miles of the new Scott river ditch, and that a Chinese company have offered to dig that part of the ditch for \$7 a rod. He has written below to the officers of the company, and will not let the contract till he shall receive an answer.

THE HOOPER LEDGE.—Cornish & Co. continue to drive their lower tunnel on the Hooper ledge. They think they are now within from 20 to 40 ft of the pay chute. In the meantime, while they have been running this tunnel which has now occupied several months, they have been taking rich rock from their shaft. The tunnel they are now running will strike the ledge about 300 ft from the surface. The rock heretofore taken from this claim has been very rich, and the owners are sanguine that there is still much more equally rich to be taken out. We trust their most sanguine anticipations may be realized.

W. A. Little, of Oak Bar, was in town a few days the fore part of this week. From him we learn that there will probably be more claims opened on the Klamath next season at Oak Bar, and between that point and the mouth of Scott river, than ever before. On that portion of the river there has been a good deal of prospecting done the present season with very encouraging results.

TRINITY COUNTY.

ANOTHER CINNABAR DISCOVERY.—*Trinity Journal*, Jan. 2: An 8 inch vein of cinnabar has been found in the bed-rock in the Wolff Placer mine, on Cañon creek. The ledge is well defined, and the work already done gives indications that it is extensive. A location has been made, and ore is now being taken out. Some specimens of the ore and castings brought to Weaverville by J. R. Driver, and left at Hartman's, are very rich, and show a large percentage of quicksilver by practical tests.

TUOLUMNE COUNTY.

THE RIVERSIDE.—*Sonoma Democrat*, Jan. 2: This mine is making handsome returns, and from what we learn will prove very profitable. It has been opened to an extent that develops a large quantity of paying ore, and the exploration is increasing the amount in sight daily. On Monday the result of 8 days' crushing was brought to town in the shape of a bar of solid gold weighing 112 ounces. The ore averages to yield two ounces of gold to the ton. When the 10 additional stamps are in motion, which will be in a few days, the amount taken out will be doubled.

Nevada.

WASHOE DISTRICT.

CROWN POINT. *Gold Hill News*, Dec. 30: Daily yield, about 600 tons, from the old ore sections, from the 600 to the 1500-ft levels, inclusive. The stopes and breasts are looking about as usual. Some very good ore is now coming from the north portion of the 1500-ft level, and the ore at that depth seeming to hold out best to the northward. Both cross-cuts at this level are still in porphyry, and are being driven ahead to find another bonanza in that direction, if possible.

JUSTICE.—The main west drift from the Waller Defeat is still driving ahead in excellent ledge matter; it is, however, being pushed forward to form a connection with the fourth station of the main Justice shaft, without present regard to the development of the ore vein. When this connection is completed, every facility will be afforded for opening out the ore developments of this important level by cross-cutting, etc.

KOSAUTH.—Shaft now down 355 ft. Sinking deeper is suspended for a few days in order to open out the station for the 350-ft level. Prospecting at the 200-ft level goes ahead as usual with good indications.

GOULU & CUARX.—Good progress is being made in the double incline winze, designed to connect the 1500 with the 1700-ft level. It will reach the 1700-ft level within the ensuing few days. The several drifts and cross-cuts throughout the mine are being pushed forward with great energy.

JULIA.—Main shaft down 1120 ft, with no water to interfere. The ground is soft and clayey, with occasional streaks of quartz, indicating a ledge near by. The main south drift at the 1000-ft level is driven ahead at the rate of three feet per day.

SIERRA NEVADA.—The water in the new shaft being well reduced, sinking deeper is now going ahead at a lively rate, in good working ground. Good ore developments are being made in the old Sacramento chimney. The best portion of this mine is evidently at the north end, near the Phil Sheridan line.

CALIFORNIA.—Cross-cuts Nos. 2 and 3, running east on the 1500-foot level, are making rapid progress toward the ore body. Cross-cut No. 2, near the southern boundary, has already penetrated the ore body to a distance of 100 feet. The quality of the ore disclosed in this drift is, for its entire length, of very high grade. The "C & C" joint shaft is sunk to a depth of 35 feet, and the hoisting works building erected over the same is nearly completed. Its dimensions are 60x60 feet. The ground is very favorable for sinking. The hoisting machinery is now being erected, and will be running by the second of January.

CONSOLIDATED VIRGINIA.—Daily yield, 400 tons. On the 1550 foot level the north drift has entered into the ground of the California mine, and is in excellent ore, as are likewise the east cross-cut near the north line, and the winze sinking below this level. On the 1500-foot level, cross-cuts Nos 1 and 2 are still progressing eastward in one of the very highest grade. The upper ore breasts on the 1300 and 1400-foot levels are looking splendidly. The new mill will commence reducing ore from the big bonanza within two days from the date of this report.

IMPERIAL EMPIRE.—The face of the drift at the 2000-foot level is getting into the west wall of the ledge, and is being pushed ahead slowly, with all due caution, and kept securely timbered in case of any sudden and extra rush of water or other emergency. The winze from the level above, continues in good ore.

DATON.—Daily yield, 60 tons. The ore sections toward the Kosauth show continued improvement in quality, and promise to yield well for some time to come.

BECKER.—Daily yield, 450 tons, from the old ore levels down to the 1400-foot. The three winzes below that level are showing well and the prospect is that the 1500-foot will open out good. The drift east from the main incline at this level is in 56 feet. The south winze on the 1300-foot level is in very good ore, and is down 23 feet from the surface, and is raised upon from the 850-foot level 127 feet. This mine is looking better generally than it was at last report, and is good for more dividends yet.

CHOLLAR-PORESL.—Daily yield 55 tons from the old workings, the car sample assays of which average \$32 per ton.

FLORIDA.—The main drift west, at the 300-foot level is in 55 feet to-day, with the face in very favorable looking material, with stringers of quartz giving low assays.

OPHIR.—Daily yield, 250 tons. The average bullion yield of the ore is constantly on the increase, owing to the better quality as well as quantity extracted. The ore breasts of the 1465-ft level especially are looking and yielding splendidly. The northeast winze at this level continues down through ore of the richest quality, and the cross-cut 33 feet below this level is also in rich ore. Both cross-cuts in the 1465-ft level are being driven ahead in very favorable material, and cross-cutting east is commenced at the 1700-ft level. So far as developed the great bonanza is found to extend north into the Ophir ground about 300 ft, with every indication of further continuance.

PHIL SHERIDAN.—The main west drift is today in 179 ft. The entire face of the drift is now in hard rock, principally quartz, which gives good assays occasionally. Mining men and experts who have seen it pronounce it good, and a rich development may be looked for at any moment.

OCCIDENTAL.—The three cross-cuts now being made from the upraise between the upper and lower levels are all in a fair quality of milling ore. These drifts have penetrated the ore body for distances of from 12 to 55 ft. The last mentioned distance is the width of the ore body in the upper cross-drifts, 100 ft below the upper tunnel. The two lowest cross-cuts, at intervals of 100 ft respectively below the first cross-cut, have not yet passed through the ore.

GLOBE CONSOLIDATED.—Main west drift driven ahead as usual. Good bunches of quartz continue to be met with occasionally, giving good promise of eventually leading to something better.

UTAH.—On the 400-ft level the drifts running in the ore vein are progressing rapidly. Cross-cuts will be started by day after to-morrow in the ore vein on this level.

YELLOW JACKET.—The north drift at the 1740-ft level is in 165 feet, and is now running in heavy ground, requiring retimbering. The east cross-cut from the drift is in 168 ft, 100 ft of which is in the ledge matter. The face of all the drifts are in porphyry and quartz.

SILVER HILL.—The drifts both north and south at the third level are running in excellent looking vein matter. The north drift of the second level is also showing well in quartz.

AMERICAN FLAT.—The drifts at the 450 and 750-ft levels still show improvement in their face. Both this and the Baltimore mine are encumbered considerably by water, and the heavy new hoisting and pumping works being erected to work both jointly are much needed.

OVERMAN.—The 1100-ft station for a drift to the ledge is opened, and drifting commenced. Sinking at the bottom of the main shaft is about being resumed.

LADY BAYAN.—Cross-cutting for the ledge progresses well, and it will be reached some time next week.

CALENDONIA.—Excellent progress is being made with the drifts at the 1000-ft level, both north and east, also with the drifting at the 1076-ft level. The south drift at the 980-ft level shows fine looking quartz in its face.

DAUNDRELLS.—Face of the east drift still in fine looking quartz with occasional spots which give good assays. It is evident that the company should sink deeper, present prospects giving ample encouragement for so doing.

ROCK ISLAND.—Winze down 59 feet, and still in fine looking vein matter with spots of good ore. Sinking the main shaft deeper is resumed. **NEW YORK CONSOLIDATED.**—Excellent progress is being made in sinking the shaft, and very flattering indications are being passed through, occasional streaks of low-grade ore being met with.

SAVOIE.—Sinking the main incline deeper progresses very favorably and drifting at the 2200-ft level is going ahead, with no important change to report.

HALE & NOCAOSS.—Daily yield, 85 tons, principally from the eighth station level. North drift and west cross-cut at the 2100-ft level making their usual progress, with no new development. The various cross-cuts at the 2000-ft level have not yet reached the west wall of the vein.

SUCOONA.—Main drift at the 550-ft level driving ahead, with face in quartz and porphyry. Indications show close proximity to the ledge.

PERCUT.—The rock in the face of the main tunnel has become much softer, being porphyry with considerable clay, allowing of faster progress.

ORIGINAL GOLD HILL.—The face of both drifts at the 340-ft level are now in low grade ore and looking well.

SENATOR.—Favorable bunches of quartz continue to be met with in drifting along the vein at the 400-ft level.

SUTRO.—Tunnel driving ahead at a lively rate and now in 807 feet from the old Utah shaft. Face in low-grade ore.

NEW YORK.—The good indications in the 250 and 700-ft levels still continue, and the drifts go ahead as usual.

MEXICAN.—Drift from the 1465-ft level of the Ophir going ahead as usual. No change.

The Empress, one of the oldest locations on American Flat, which has been lying for years undeveloped, now is in the hands of parties who are able and willing to find out what its real merits call for. Work is once more resumed upon it, and the old shaft is being cleaned out and re-timbered, preparatory to sinking deeper. The *News* says that the ground about the top of the shaft is being graded off for efficient hoisting works, the machinery for which is engaged and will soon arrive.

THE GOULD & CURRY.—The report of the treasurer of this mine for the last fiscal year shows that four assessments had been made, aggregating \$310,713.29. Other items had swelled the receipts to \$328,224.54. For the sale of assaying materials \$66 was received; for hoisting ores and rock, \$5,751.50. The cash indebtedness on the 30th was \$61,838.15; cost of insurance, labor and materials, \$235,598.08; general expenses, salaries, etc., \$19,502.15; minor expenditures, legal fees, etc., \$45,796.

IN THE CROWN POINT mine two new levels, one and two hundred ft below the present lowest working level will be opened before long, giving plenty of room for the ore vein, which is somewhat contracted at the 1500-ft level, to widen out into a comfortable continuation of the great bonanza, which has yielded so many millions thus far.

Jute.

This is undoubtedly one of the products destined to figure in the programme of diversified farming in California. Although some attention has been given to this matter during the last two years, it may still be ranked among agricultural experiments. We have endeavored to "draw out" those who are experimenting in the culture of jute, and have them communicate the results through the PRESS. But very little practical knowledge, it is evident, has yet been secured, and those who possess that little are quite uncommunicative on the subject. Judging from the extent and character of the inquiries received by us concerning jute, and the difficulty in obtaining the desired information, we are convinced that the growth of interest in the matter is increasing much faster than that of the plant itself.

In Southern agriculture the subject occupies precisely the same position as with us. The farmers there are making the same efforts to curtail the proportions of the cotton product, that we are using to reduce those of the wheat crop. Among the means by which they hope to effect this curtailment, the cultivation of jute figures conspicuously; more so than with us. The Jute company of New Orleans has been in active operation for some time, and is using every means to induce planters to substitute, in a measure, this crop for that of cotton; and to place the material before the manufacturers of the country. The President of this company a short time since sent to the Department of Agriculture at Washington, specimens of jute and its fabrics raised and manufactured in Louisiana. They consisted of jute filament, rolled, after cleaning by machinery; jute rope, crude as it comes from the machine; and jute rope made of rotted jute. The President stated that the jute was acknowledged to be 50 per cent. superior to the Indian article. A planter, writing from North Carolina, says that the ground was prepared as for cotton, and the seed dropped twelve inches apart; and, as the spring was a very wet one, the seed lay dormant for three weeks. The plant grew to a height of thirteen feet, with branches from five to seven feet long. The land was ploughed twice, and hoed once. It was cut in October and thrown into water, where it remained to rot three weeks; the bark was then easily stripped from bottom to top. A specimen of the fibre was exhibited at the State fair, and pronounced very fine by persons who were familiar with its culture. Bottom lands of North Carolina could be made, it is affirmed, to produce, by manuring, as much as 3000 pounds per acre. A planter in Georgia, also, who has succeeded well in an experiment in raising jute, says that if five cents per pound can be netted, more can be made by raising jute than cotton. He planted about May 1; the seed germinated freely, and the plants grew finely on rather poor land, attaining a height of over ten feet by September 19.

The attention of England is already directed to the impetus given to jute culture in this country. Although they declare that there are no indications that this fibre will be raised in the United States to an extent that will jeopardize the prosperity of the jute industry of Bengal—the main source of jute supply for England—the consideration of the subject has induced the Government in India to appoint a commission to inquire into the culture, etc., of the jute plant. They were evidently incited to this by the superiority of the American product, and with the characteristic willingness of Englishmen to acknowledge manifest superiority, and the unwillingness to play second to anybody in anything, they instituted a thorough investigation of the subject.

The report submitted by this commission is complete in every respect; containing much information that will be extremely interesting to those who are simply curious in the matter, and deserving the careful consideration of those who view the subject from the commercial and manufacturing stand points; while those who wish to embark in its culture will be able to obtain from it many points of practical utility. We therefore give the following synopsis of the report, as published in a recent number of the *British Trade Journal*:

"As to the origin of the word *jute*, concerning which there has been so much dispute; it is suggested that the modern word is simply the Anglicised form of the Orissa *jhot*, and the ancient Sanskrit *jhat*. As to the precise plant which yields the fiber, the commission has shown that the jute of commerce is yielded indifferently by two distinct species of *Tilacea*, the *Corchorus olitorius* and *Corchorus capsularis*. The plants are extremely alike in appearance, leaf, color, and growth, and differ only in their seed-pods, those of the *C. capsularis* being short, globular, and wrinkled, while those of *C. olitorius* are the thickness of a quill, and about two inches long. Both plants are annual, and grow from five to ten feet high, with a stalk about the thickness of a man's finger, seldom branching except near the top. The leaves, which are of a light green color and serrated, are four or five inches long, and taper to a point. Several other species of the same plant are said to yield *jute*, but are not cultivated for the fiber, the species already named alone yielding the real jute. This fact was established by the commission, by a series of experiments in the Royal Botanical Gardens with seeds obtained from all the districts in which the fiber is grown. The results showed that the *jute* of commerce is the produce of

one or the other of the two plants named, and of them only.

In lower Bengal, the two species appear to be grown indifferently; but in the central and some of the eastern districts, the *C. capsularis* largely predominates, while in the neighborhood of Calcutta it is the *C. olitorius* that is chiefly cultivated. The well known Lakhimpore jute of Hooghly and the 24-Pergunnahs, known also as *desi jute*, is the produce of this latter species. The plant has been cultivated from time immemorial in the lower provinces, but its export is a modern industry, although the fiber has been cultivated largely for home use, and for the manufacture of gunny from a very remote period. One or other of the two plants has been found in no less than forty-seven out of the fifty-eight districts of the Presidency. The attention of the Commission was specially directed by the Government to the importance of ascertaining what description of soil was most favorable to the growth of the fiber. The evidence collected upon the point is conflicting. A light sandy soil is not suited to it, and it seems most to flourish in a hot, damp atmosphere, with a heavy rainfall and rich alluvial soil. The seasons of sowing and growing appear to be generally the same as those for the early rice crop of Bengal. The oftener and more thoroughly the land is plowed, and the more manure, the better. The seed is sown broadcast from the middle or end of March to the beginning of June, and the plant cut from the middle of August to the middle of October, and in some of the districts earlier. The Commission direct prominent attention to the extreme carelessness of the cultivators in the selection of the seed. In most instances a corner of the field, or a few stunted wayside plants are left to produce it, not the slightest attempt being made to select it; and if in these circumstances a real deterioration of the plant had taken place, a fact which the commission doubt, little wonder could have been expressed. Neither selection nor change of seed seems to be resorted to, and if the attention of the Government is ever directed to improving the cultivation of this plant, its first step must be a reform in this fundamental point of good husbandry. The acreage under jute in the great producing season of 1872 was 921,000. The area is said to have been no more than 517,000 acres in 1873. The northern and eastern districts may also be said to engross the cultivation, showing a total area of 800,000 acres under the plant in 1872, against 125,000 only in the rest of the Presidency. The suggestions of the improvement of the staple are confined to the selection of the seed, to the observance of a more careful rotation in growing the crop, and to the improvement of the processes for cutting and steeping the fiber. The influence of the cultivation on the condition of the people appears to have been good. The testimony is uniform that it has enriched the cultivators, while the deleterious effects of the manufacture upon their health seems to be very problematic. As to an alleged deterioration of the staple, the commission attribute this belief to the fact that the high prices which have prevailed of late years have stimulated the production of large quantities of inferior or badly-prepared jute. It is not that there is less good jute produced than formerly, but that a larger proportion of inferior fiber grown on any and every soil has come into the market under the stimulus of prices; and that when the quantity grown is large the care devoted to its preparation is comparatively small. The commission record their judgment that there is nothing to show that there has been any deterioration, in the character of the jute, or any general falling off in the quality of the fiber. The local manufactures of the fiber into cordage and twine, and into gunny cloth, and gunny bags, are described in their report at length; and the commission have shown that it is used for paper-making in several districts.

THE OMAHA MINE.—In a review of the mining situation at Grass Valley, the *Union* speaks as follows of the Omaha mine: It is situated south of Grass Valley on Wolf creek, and about three miles distant from the town. It is owned by an incorporated company, which has its principal place of business at Sacramento. Sixteen miners are at present employed and \$3 per day per miner are paid. The cost of sinking so far per foot has been \$25. The cost of drifting per foot has been \$10, and the cost of stopping per ton has been \$6. The cost of extracting ore per ton has been about \$10 and the cost of milling the ore per ton has been \$3 50. The milling is done at a custom mill. The number of tons which have been worked is 100, and gave an average yield of \$21 per ton. The percentage of sulphurets is about 1.5. The total bullion product has been \$2,500. The length of the location is 1400 feet and the course of the ledge is north and south, with a dip to the west at an angle of 32 degrees. The length of the pay zone as far as explored is 170 feet, and the vein has an average thickness of 15 inches. The country rock is serpentine. The work is done through a shaft which is 260 feet deep. The ledge in the bottom of the shaft is fully three feet thick and shows free gold in great quantities besides good sulphurets and general good quality of rock. The walls of the ledge are well defined and smooth. Two levels have been opened and these are, together, of the length of 255 feet. The hoisting works are run by water power and cost \$1,500. M. Dodsworth is the Superintendent.

DYING UP.—In Trinity county everything is said to be drying up, and both miners and farmers are anxiously looking for rain.

Panamint District.

The *Inyo Independent* says: During a recent visit to Panamint we took occasion to make as thorough an examination of a number of its ledges as could be done in three days climbing, and by hammering croppings at short intervals from the beginning of one location, though step by step, to the next and the next. The result of this persistent hammering and breaking rock was to prove conclusively that there is scarcely a point in all that vast range of exposed quartz where "metal" in fair quantities, varying from a "color" to \$2,000 to the ton, cannot be found. It appears as though there was no portion of the croppings in the limestone formation that was not more or less impregnated with mineral. Nor is there an opening anywhere that does not show a pay streak of a few inches in width of very high grade ore.

As our examinations extended over several miles of croppings, with almost uniform results wherever broken into, no matter how unpromising in outward appearance, we conclude that there is enough near surface ore close to Surprise canyon to maintain quite a city for a half a dozen years or more to come. There need be no fear on this point. But it is prophesied by White Piners and others, that since the best and greater portion of the mines lie in limestone the bottom will soon be reached—that no pay ore will be found at any considerable depth. Such may be the case, but there is no reason obvious to a common understanding why it should. On the contrary, it would seem to be an almost absolute certainty that the pay ore runs down to immense depths. There can be no question that these are true fissure veins; they may be divided into two distinct veins; the mother vein, on the north side of the canyon, known as the Jacob and Stewart's Wonder, cuts straight across deep gulches and lofty hills for at least a mile and a half, with scarcely a break in its whole length. The only perceptible difference in the prospect, whether made at the lowest point of depression or the highest elevation. The same is true of the other grand vein, which, from its most noted location may be called the Wyoming series. This lies on the opposite side of the canyon, with which and the Wonder ledge it runs nearly parallel, but at a greater altitude. This ledge is cut down at least a thousand feet deep in one place, and about half as deep in several others. It cuts far into the slate on the east, the only portion that appears to be barren, and extends over two miles southwesterly, across deep gulches, through the lime, into still another formation.

Branching from it are numerous ledges, all large and showing high grade ores, these in turn cutting across hill and gulch a mile down to the main canyon itself. Counting these numerous spurs, the connections of which are easily traced, this mother vein exposes several miles of the very richest croppings. At the lowest depth yet attained, which is on the Wyoming, and is about fifty feet, we saw rock taken which assayed \$915 to the ton, and there was apparently plenty of it. The next lowest, about twenty feet, on the Esperanza, a large spur or cross ledge, there was about a foot of \$325 rock. These are fair average assays of the pay streak proper in hundreds of openings throughout the district. The same openings show from ten to twenty times as much ore which will probably average \$50 to the ton—a class of ore which, with proper facilities, can be worked with fair profit. Outside of these two veins are numerous other locations, none of which we saw, but one or two of which, if no more, are said to be as promising as the best of the series. One of these is the Sunrise, lying in the slate, and possibly the eastern extension of the Wyoming. The Sunrise is the only prominent mine yielding free milling ores—all chlorides. But lack of space forbids any notice in detail of even the most prominent locations of the district.

Owing to the nature of the ground, the town site of Panamint is somewhat circumscribed, but much less so than is commonly reported. There is room there for a city of at least 10,000 without uncomfortable crowding. Its present population, all classes, will approximate 1,500. The business of the place, outside of mining, consists nearly of restaurants, stores and saloons. There is a present sufficiency of them. There are inducements for the establishment of some other branches, particularly a good hotel, one of which, however, will soon be ready for business.

As soon as the concentrating mills are put in operation, which will require at least three months yet, there will be a demand for many more miners, mechanics and common laborers, but at present there is quite enough.

The Surprise Valley Mill and Water company have done an immense amount of work, cutting roads and other permanent improvements, and are now but just beginning to do some systematic mining. They will soon have their principal mines opened at half a dozen levels each, and find bottom and prove them almost the finest mines ever seen. Ton after tons of Hercules powder is being used in these openings, blasting being necessary at every step. The reports from these blasts reverberate and fairly ring in the echo, sounding as full and loud as a heavily charged 24-pounder. The company have already expended nearly \$1,000,000, and expect to expend about half as much more before they get fairly to mining and reducing ores. Numerous other companies are preparing for operations on a large scale, and altogether the future of Panamint is exceedingly promising.

It will afford a great basis for stock operations; in this it will hardly stand second to the Comstock itself. Some thirty incorporations are preparing for legitimate mining, but no doubt with the ulterior view of running "adits" in the San Francisco Stock Board as soon as their mines can be made to give them a reliable base.

The Eureka Mine.

From an article in the *Grass Valley Union* we take the following concerning the Eureka mine, situated about two miles east of Grass Valley, which employed during the year, the average of 80 miners. The wages of these have been \$3 per day to the man. The cost of sinking, per foot, in exploring has been about \$65, while the cost of drifting has been about \$25 per foot. The cost of "stopping" has been about \$10.50 per ton of ore. Milling the ore costs \$2.61 per ton; the company owning its own mill. The number of tons extracted and worked during the year is 8,130, the average yield of which has been \$25 per ton. The percentage of sulphurets in the rock amounts to 1.5. The total bullion product has been, for the year, about \$205,780. The Eureka's location is 1,680 feet, for which the company has a patent. The course of the ledge is nearly east and west, and the dip is towards the south. The length of the pay zone is about 1,000 feet, with a ledge of four feet in thickness. The country rock is slate and serpentine. The mine is worked through a shaft, which has a total depth of 1,250 feet. There are eight levels opened, and the total length of drifts is 9,000 feet. The cost of the hoisting works is \$48,000. At the mill a sixty horse power engine is in use, and the number of stamps is 30, each of which weighs 850 pounds. These are dropped, each, 65 times per minute, and the drop is ten inches. There are two pans and two sulphuret concentrators in the mill. The cost of the mill was \$30,000, and is capable of crushing 65 tons of ore in 24 hours. The sulphurets are treated by the chlorination process. All the stamps of the mill have not been employed during the year. The lower portions of the mine do not show good pay rock, but explorations which are now going on may result in something good. The Eureka went into operation October 1st, 1865, and up to and including the 30th of September, 1874, had taken out bullion to the value of \$4,273,148.49. During that time it paid dividends to the amount of \$2,054,000. On the 1st of October, 1874, the company had on hand in cash and value of supplies the sum of \$101,646.73, which will enable them to explore the ledge to a much lower depth than has yet been reached. Mr. Wm. Watt is the Superintendent of the mine, with Mr. James Gluy as Foreman.

Lively Times on the Comstock.

Notwithstanding, says the *Virginia City Chronicle*, that the present is the dull season, there is an unprecedented demand for houses. Small tenement dwellings are scarcely to be had at any price, and rents are rapidly advancing. Lodging house keepers have applications daily for rooms that they cannot fill, and the ingress of emigrants from the East still increases. The reputation of the Comstock still continues, and Eastern papers are filled with sneering remarks concerning the recent rich discoveries, which are compared to the bogus diamond wedding, which lately took place in Brazil. People east of the Mississippi have but very little idea of mining, and many are of the opinion that silver comes out in solid chunks and that silver hars are cut out bodily in the interior of the earth. However, Nevada does not depend on the East for the sinews of trade. Silver and gold is currency itself, and it is not necessary to hunt for a market, as is the case with any other product. As a natural result a mining community is the most independent in the world, and as long as the residents of Virginia City have beneath their feet millions of dollars in silver ore, they can afford to keep their own counsel and pay no attention to the incredulity of the novices of Eastern States.

The new shaft on the dividing line between the California and Consolidated Virginia mines is already down a depth of twenty feet. The ground on the surface is being graded off for some distance about the mouth of the shaft, and preparations are being made to put up hoisting works which will contain a seventy horse-power engine.

The owners of mining locations are busily engaged all over the State in doing work to keep their claims good, while others are keeping themselves in reserve to make re-locations of eligible properties as soon as the first of January arrives. There will undoubtedly be many conflicts over mines which different parties are preparing to jump.

From present indications the new mill of the Consolidated Virginia will be started up within the next fortnight. Steam was turned on yesterday. An inspection shows that the machinery is the finest in the State. When its sixty stamps start upon ore from the new bonanza, the results will be satisfactory to all concerned. There is talk of building a new mill by the California company in the same neighborhood.

PAPER BARRELS.—The paper barrel business seems likely to amount to something. A manufactory is being erected in Rochester which will turn out six hundred barrels a day. They are much lighter and more durable than wooden barrels, and take very well with the public.

GOOD HEALTH.

Wet and Dry Bathing.

If any one in these days will exercise in the open air, so that each day he will perspire moderately, and if he will wear thin undergarments, or none at all, and sleep in a cold room, the functions of the skin will suffer little or no impediment, if water is withheld for months. Indeed, bathing is not the only way in which its healthful action can be maintained by those living under the conditions at present existing. Dry friction over the whole surface of the body, once a day, or once in two days, is often of more service than the application of water.

The reply of the centenarian to the inquiry to what habit of life he attributed his good health and extreme longevity, that he believed it due to 'rubbing himself all over with a cob every night,' is significant of an important truth. If invalids and persons of low vitality would use dry friction and Dr. Franklin's 'air bath,' every day for a considerable period, we are confident they would often be greatly benefited. Cleanliness is next to godliness, no doubt, and a proper and judicious use of water is to be commended; but human beings are not amphibious. Nature indicates that the functions of the skin should be kept in order mainly by muscular exercise, by exciting natural perspiration by labor; and, delicious as is the bath and healthful, under proper regulation, it is no substitute for that exercise of the body, without which all the functions become abnormal.

POISONED CONFECTIONERY.—A gloom was recently thrown over the town of Placefield, Conn., by the death of a twelve-year-old daughter of Mr. Edward Markland. The immediate cause of her demise was the eating of candy in which there was arsenic. Some three weeks ago the girl in company with two girls named respectively Miss Bunnell and Miss Hemmingsway, attended an evening party, at which, by way of entertainment, was offered confectionery purchased in the town of Forrestville, a portion of which was originally manufactured in the city of New Haven. They partook heartily of the same and soon after were taken violently sick. The sufferers were attended by Dr. Woodward of this place, who, on examining the symptoms, pronounced the poison to be arsenic, and that it was contained in the candy. Under his treatment the two last named girls were partially restored to health, though they are not yet considered out of danger. But with Miss Markland the case was different. Medicine seemed to have no healing effect upon her. Previous to death she literally suffered many deaths. Her tongue became frightfully swollen, and some time before she breathed her last inflammation seized upon her eyes and rendered her totally blind. During it all the little creature was perfectly conscious, and patiently endured the most excruciating pains till death brought relief.

A SINGULAR CASE.—The Chicago physicians are puzzled by Michael Finnegan, a patient in one of their hospitals. During more than two months he has lain rigidly in bed, seldom moving a muscle, and yet shows no other signs of illness than this strange impassiveness. He is fed with liquids poured down his throat; his limbs are moved with difficulty by the attendants, as though the muscles had become fixed, and he never speaks, although his eyes move, and at times he seems to be sensible. The physicians believe it to be a genuine case of catalepsy, or of hysteria and simulated catalepsy. There have been instances of cure of both these disorders by fright, and an experiment was made on Finnegan. The physicians talked in his presence of cutting his jugular vein, so as to kill him and end his suffering, and after a great show of preparation scratched his neck with the point of a knife, but he exhibited no fright.

CURE FOR CORNS.—The safest, the most accessible, and the most efficient cure of a corn on the toe is to double a piece of thick, soft buckskin, cut a hole in it large enough to receive the corn, and bind it around the toe. If in addition to this the foot is soaked in warm water for five or more minutes every night and morning, and a few drops of sweet oil or other oily substance, are patiently rubbed in on the end after the soaking the corn will almost infallibly become loose enough in a few days to be easily picked out with a file. This saves the necessity of paring the corn which operation has sometimes been followed with painful and dangerous symptoms. If the corn becomes inconvenient again, repeat the process at once.—*Hall's Journal of Health.*

HEALTHFULNESS OF APPLES.—The frequent use of apples, either before or after meals, has a most healthful effect upon digestion. Better eat less meat and more fruit. An eminent French physician thinks that the decrease of dyspepsia and bilious affections in Paris is owing to the increased consumption of apples, which fruit he maintains is an admirable prophylactic and tonic, as well as a very nourishing and easily digested article of food. The Parisians are said to devour one hundred millions of apples every winter—that is, they did before the war. Whether this estimate is true or not, the French are extravagantly fond of apples and other fruit.

CARE OF THE EAR.—The *Scientific American* thinks that the ear is quite as liable to injury from drafts of air as from cold water. The modern style of cutting the hair in men, and of arranging the hair of women is much to be deprecated, because it was intended by nature that the hair should fall over the ear, and thus form a protection to it. But as we cannot throw down so great a goddess as fashion, we must use care and artificial means for the preservation of this delicate organ. If sitting in a draft is unavoidable, the handkerchief should be applied to the ear exposed, or a pledge of cotton inserted within it. The ordinary manner of washing the face does no harm to the ear, because the canal leading to the drum of the ear is partly occluded by wax, and water does not penetrate far; but all swabbing of the ear, whether with dry cloth or lint moistened with hot or cold water, or other fluid, is by no means to be advised, as it removes the wax, the necessary safeguard to the internal ear.

EFFECT OF IMAGINATION.—A young man walked into an Indianapolis drug store the other day, and called for fifty cents' worth of strychnine. The clerk, suspecting his object, gave him a harmless dose of sugar of milk. The youth swallowed it at once and sat down to die. To the surprise of the clerk, he soon showed every indication of poisoning, and he thinks that had he not told him of the harmless nature of the potion, he would have died from mere imagination.

IGNORANT PRACTITIONERS.—It is said that Montreal, Canada, has in the last 11 months lost one and one-half per cent. more of its population than the city of New York, by death, and of this rate upward of 12 per cent. has been from small-pox. Singular to say many of the doctors oppose vaccination, which accounts for this mortality. The *Montreal Star* appeals to the clergy for aid against the doctors who are so far behind the age in their practice.

USEFUL INFORMATION.

MYSTERY OF THE LAKES.—Lake Erie is only 60 or 70 feet deep; but Lake Ontario, which is 592 feet deep, is 240 feet below the tide level of the ocean, or as low as most parts of the Gulf of St. Lawrence, and the bottoms of Lake Huron, Michigan and Superior, although the surface is not much higher, are all from their vast depths, on a level with the bottom of Ontario. Now, as the discharge through the river Detroit, after allowing for the probable portion carried off by evaporation, does not appear by any means equal to the quantity of water which the three upper lakes receive, it has been conjectured that a subterranean river may run from Lake Superior, by the Huron, to Lake Ontario. This conjecture is not improbable, and accounts for the singular fact that salmon and herring are caught in all the lakes communicating with the St. Lawrence, but no others. As the falls of Niagara must have always existed, it would puzzle the naturalist to say how these fish got into the upper lakes without some subterranean river; moreover, any periodical obstruction of the river would furnish a not improbable solution of the mysterious flux and reflux of the lakes.

BLASTING ACCIDENTS.—A HINT WORTH REMEMBERING.—Most people are familiar with the fact that friction of the feet on a dry carpet or other non-conducting floor is capable of so charging the person with electricity that a spark may be drawn from almost any part of the body. Thus it is a common trick to light the gas with the finger after shuffling along the floor. An exchange calls attention to the circumstance that the facts just stated may prove to be a frequent but little understood cause of accidents in blasting, and which applies to powder as well as nitro-glycerine. The blaster, not aware that he is often a walking charge of electricity, proceeds to his work, inserting cartridge after cartridge of nitro-glycerine, until he comes to the last, which is armed with the electric fuse. The moment his hand touches one of the naked wires, a current of electricity may pass from his body through the priming, and produce an explosion. Hence, before the blaster handles the wires he should invariably grasp some metal in moist contact with the earth, or place both hands in contact with the moist walls of the tunnel or shaft in which he is working.

TO KEEP ICE FROM WINDOWS.—This advice is hardly appropriate for our California climate under ordinary circumstances; but if the cold continues to increase as it has for the last two weeks, it may be found useful even here: Take an ordinary paint brush or sponge and rub over the glass once or twice a day, a little alcohol. This will keep the glass as free from ice as in middle of summer, and give as fine a polish as can be got in any other way.

A PROCESS OF PULPING LEATHER IN ENGINES, similar to those used for beating rags in a paper mill, is now in use in Massachusetts. By rolling into sheets under considerable pressure, a product of great tenacity, homogeneity, and closeness of texture is obtained which is, moreover, perfectly waterproof.

SINGULAR FACT.—When the beautiful feathers on the breast of a humming bird are examined under the microscope, no colors are to be seen. The brilliant tints come from the display of light upon the bird under different angles.

COMBUSTION OF COAL.—Combustion is a chemical process, consisting usually in a combination of the elements of our atmosphere (the oxygen) with the fuel. The main substance of fuel, especially when it is coal, is carbon, and the chemical equivalent of this, 12, combines with two chemical equivalents, 2x16, or 32 parts by weight of oxygen, which is equal to two and two-thirds parts of oxygen for every part of carbon. A pound of coal requires thus two and two-thirds pounds of oxygen for its perfect combustion; as no one pound of this gas under ordinary atmospheric pressure occupies a space of some 12 or 13 cubic feet, or two and two-thirds pounds of oxygen a space of 34 cubic feet, which in the air is diluted with four times this amount of nitrogen, it requires five times this quantity, or not less than some 170 cubic feet of fresh common air to furnish the oxygen required; it is therefore necessary to pass 170 cubic feet of air through the furnace gates in order to secure the perfect combustion of every pound of coal. If less air is passed, the combustion is retarded, while an excess of air cools the furnace.

SPONTANEOUS FIRE IN HAY.—A somewhat remarkable case of spontaneous combustion occurred last fall at Aztalan, Wisconsin. Mr. James Payne, a well known farmer of that town, some time since cut and put into his barn about ten tons of clover hay, which was quite in a green condition. A few days afterward smoke was seen issuing from Mr. Payne's barn, and it was soon discovered that the clover was on fire, and only by the most strenuous exertions of himself and neighbors were the flames finally extinguished. The fact of spontaneous combustion from the fermentative heat of uncured clover, is admitted by all as being the cause of the fire.

DETECTION OF ADULTERATED WINE.—M. De Cherville gives the following useful hints for deciding whether red wines are artificially colored or not: "Pour into a glass a small quantity of the liquid you wish to test, and dissolve a bit of potash in it. If no sediment forms, and if the wine assumes a greenish hue, it has not been artificially colored; if a violet sediment forms the wine has been colored with elder or mulberries; if the sediment is red, it has been colored with beet root or Pomsambuco wood; if violet red, with logwood; if yellow, with phytolac berries; if violet blue, with pivet berries; and if pale violet, with sunflower."

PROFESSIONAL STATISTICS.—In England there is one lawyer for every 1,240 of the population; France, one for every 1,970; in Belgium, one for every 2,700; and in Prussia, one for every 12,000 only. Another curious fact is that in England the number of persons belonging to each of the different professions is nearly the same. Thus there are 34,970 lawyers, 35,488 clergymen, and 45,955 physicians. In Prussia, on the other hand, there are 4,809 physicians to only 1,362 lawyers.

CHINESE FISH-HATCHING.—A curious mode of fish-hatching is said to be followed in China. Having collected the necessary spawn from the water's edge, the fishermen place a certain quantity in an empty hen's egg, which is sealed up with wax and put under the sitting hen. After some days they break the egg, and empty the fry into water well warmed by the sun, and here nurse them until they are sufficiently strong to be turned into a lake or river.

A RECENT patent for a map consists in having those portions intended to represent the rivers, lakes and oceans filled with actual water. This is done by attaching the map to a back of wood of sufficient thickness. The rivers, etc., are dug out, filled with water and glazed. Such maps may be hung upon the wall in the usual manner.

FIRST USE OF POSTAL CARDS.—Prof. Emanuel Herman, of Vienna, first introduced postal cards. They were used in England, Germany, and Switzerland in 1870, in Belgium and Denmark in 1871, and in Norway, Russia and the United States in 1872-3. In some foreign countries a card is attached on which an answer may be returned.

A CHAIN of compressed cakes of gun cotton tied around the trunk of a large tree and exploded will, it is stated, cut it down instantly by the violence of its action. The cut through the trunk is as sharp as that made by the keenest ax.

THE Brooklyn tower of the East river Brooklyn bridge was completed on the 16th of December. Its total height is 268 feet—48 feet higher than Bunker Hill monument. It presents a very imposing appearance; we hope it will not prove a tower of folly.

USE FOR SNAKES.—A farmer in Washington county, Ky., has found a practical use for a snake. For two years he has had one shut up in his corn crib, and all that time not a single mouse has been seen there.

EUROPEAN LANGUAGES.—A recent calculation, relative to the European languages shows that English is spoken by 99,000,000 of persons, German by 45,000,000, Spanish 55,000,000 and French by 45,000,000.

ELKSkins dried and cut in slips make very strong half lacings.

DOMESTIC ECONOMY.

Importance of the Inorganic Constituents of Food.

The bodies of animals in a state of health, though chiefly composed of organic substances, contain, nevertheless, always certain inorganic salts, either in combination or solution. The soft parts of the bodies are here intended, and not the bones, which are, of course, largely composed of inorganic matter. Mr. J. Forster has recently described some interesting experiments on the effect of gradually reducing the quantity of these salts in the system, by feeding animals with food of an entirely nutritious description, but completely deprived of such salts. The food employed consisted of albumen, starch and fat, with entirely pure water. Animals thus treated suffer gradual derangements of the functions of various important organs, which derangements go on until the power of assimilation of the food taken is so far reduced as to prevent the proper repair of the ordinary waste of the system. The natural consequence of this would be to produce decline or death. But death usually ensues before it could be brought about by a cause so slowly acting, since the deficiency of salts, by arresting some of the processes necessary to life, precipitates the destruction of the organism before it could perish by exhaustion. Exhaustion is the effect produced upon the muscles by withholding salts, but in the nerves there appear, first, increased excitability, and then paralysis of the nerve centers. The quantity of salts necessary in the food is less than has heretofore been supposed, but further experiments are necessary to determine its exact amount.

COCKS' COMBS AS FOON.—The combs of Spanish and Leghorn fowls are sold in some parts of Europe as choice delicacies for the palates of those who sigh for fresh appetizers. Under the name of "Cretes de Coq," a supply of these morsels has been recently imported from Paris. The combs are of large size, both single and rose, and are put up in white vinegar, in long tubular glass bottles, holding about a pint, sealed with black wax. When we say that these small bottles cost at wholesale in Paris more than a dollar in gold each, the reflection is forced that many a large combed rooster may in future be sacrificed to Mammon, as many were offered up to Esculapius. There are enough large combs in the yards of some of our breeders to make a fortune if they could be utilized. We hope, however, the combs on the Mediterranean coast will be reduced in size, as many large ones amount to positive deformity.—*Poultry World.*

MISS SEDOWICK has asserted that the more intelligent a woman becomes, other things being equal, the more judiciously she will manage her domestic concerns. And we add that the more knowledge a woman possesses of the great principles of morals, philosophy and human happiness, the more importance she will attach to her station, and to the name of a good housekeeper. It is only those who have been superficially educated, or instructed only in showy accomplishments, who despise the ordinary duties of life as beneath their notice. Such persons have not sufficient clearness of reason to see that domestic economy includes everything which is calculated to make people love home and be happy there.—*Germanian Telegraph.*

BEEF TEA.—Take one pound of juicy, lean beef—say a piece from the shoulder or the round—and mince it. Put it, with its juice, into an earthen vessel containing a pint of tepid water, and let the whole stand for one hour. Then slowly heat it to the boiling point, and let it boil for three minutes. Strain the liquid through a colander, and stir in a little salt. If preferred, a little pepper or allspice may be added.

Mutton tea may be prepared in the same way. It makes an agreeable change when the patient has become tired of beef tea.

BEEF CLUBS.—Beef clubs are in order in some parts of the west. A dozen or 20 farmers combine and each one agrees to furnish a fat steer at a time allotted him. This is divided among the members of the club. Accurate accounts are kept, and at the end of the year a settlement made. The quality of the beef is regulated by the proportion of tallow to the meat, a fine being levied if it falls below a certain per cent.

SPONGE GINGERBREAD.—One cup of sour milk, one cup of molasses, one half cup of butter, two eggs, one and one-half teaspoonsful of salaratus, one tablespoonful of ginger, flour to make it thick as pound cake. Put the butter, molasses and ginger together and make them quite warm, then add the milk, flour and salaratus and bake as soon as possible.

DRIPPING CAKE.—Mix well together two pounds of flour, a pint of warm milk, and a tablespoonful of yeast; let it rise about half an hour; then add half a pound of broken angar, a quarter of a pound of currants, and a pound of good fresh beef dripping; boil the whole well for nearly a quarter of an hour, and bake in a moderately hot oven.

The Mining Laws.

Within the past week no doubt many thousand mining claims have been re-located, by reason of forfeiture of claims by the owners not complying with the provisions of the mining laws of the United States. The fact that claims have been located by parties not original owners, has no doubt created considerable dissatisfaction in many places. There seems to be, moreover, a difficulty among the miners concerning the correct interpretation of the law, and it is to be expected that considerable litigation will arise from disputes as to ownership of mines. A correspondent, one of many, writes to us from Monterey, Alpine county, and says: "On Jan. 24, 1875, the writer re-located a claim in this town, which claim at the time had not received the amount of work upon it required by the law which took effect upon the advent of the new year. Does the re-location hold good?"

It is to be supposed that by this time the miners know the amount of expenditure required on their claims annually. On claims located after May 10, 1872, \$100 of work must be done or improvements made each year; and on claims located prior to May 10, 1872, \$10 worth of work for each 100 feet on the vein, until a patent is issued. The time required for first annual expenditure on claims located prior to the passage of the Act, was extended twice, the last time to January 1, 1875. Those claims not patented were subject to the provisions of the law requiring expenditure and if the work was not done is most decidedly open to relocation. If the claim referred to by our correspondent had not had the work done upon it, or the improvements made which were required, his re-location most certainly holds good.

However, even if located after the passage of the Act of May 10th, 1872, and the annual expenditure had not been made within the year, it was open to relocation in both cases; provided, however, that the original locators had not commenced work upon it on the 1st of January. If they only did five minutes work on it on that day, however, their chances are good for holding, as the law says the claims can be held provided the original locators, their heirs or assigns have resumed work on the date above mentioned. It is not to be said that they must do all the work continuously from that day, but

simply that they must have "resumed work." Sticking to the letter of the law they may do \$50 worth of work on the first day of the year, and \$50 on the last and still hold their ground. This view is maintained to be right by many competent judges.

Our correspondent also says that another claim was jumped in which is a large quantity of valuable machinery, hoisting works, etc. He wants to know if the location holds whether the machinery becomes forfeit also. To this we may answer assuredly not. The Government owned the land and gave it to be worked on certain conditions; when the conditions are not fulfilled, the Government simply reserved the right to take it back and give it to some one else who will fulfill the conditions. It never owned the machinery and has nothing to do with it, that being property entirely out of the Government reach. There is no mention in the law of forfeiture of machinery. If the claim is not worked it may be re-located; but you can't originally locate machinery, so you can't re-locate it.

A decision made last month by the Department in a hypothetical case may be of interest, or decide some important question among the miners. It is as follows:

"A claim located prior to March 10, 1872, upon which the amount required by the Act of that date shall since have been expended will not be subject to re-location January 1, 1875, provided that the claimants have complied, in all respects, with the local laws."

That is as much as to say that provided the first annual expenditure has been made at any time since May 10th, 1872, the claim could not be relocated on the 1st of January even though the work was not done in 1874. Such claims are safe until January 1876.

Another correspondent says he has located 1500 feet on a ledge, then moved 10 feet away from the end of his claim, sunk a shaft and claimed 1500 feet more. He wants to know whether he can hold both. He cannot hold both claims in any such way, as the law expressly states that a miner can only locate 1500 feet on one vein. But he can get some one else to locate the other claim in the usual way, and then buy him out and so get possession legally of the whole 3,000 feet. But what a man wants with 3000 feet of a ledge is a puzzle. It is hard work enough generally to take care of 1,000 feet.

The Bullion Product.

The total bullion product of the Pacific States and Territories for the year 1873 was \$72,258,693. This year it was \$74,401,055 showing an increase of \$2,142,362 over 1873. Jno. J. Valentine, General Superintendent of Wells, Fargo & Co.'s Express, who computes the most reliable statistics on this point writes as follows:

We hand you herewith a copy of our annual statement of precious metals produced in the States and Territories west of the Missouri river, including British Columbia, during 1874, which shows an aggregate yield of \$74,401,055, being an excess of \$2,142,362 over 1873. California, Nevada, Utah, Colorado and British Columbia increased; Oregon, Washington, Idaho, Montana, Arizona and Mexico (west coast) decreased. The increase in Nevada and Colorado is merely nominal, but in California and Utah it is \$3,100,000, three-fourths of which is to the credit of California.

STATES AND TERRITORIES.	Gold Dust and Bullion by Express.	Gold Dust and Bullion by other Conveyances.	Silver Bullion by Express.	Copper and Base Bullion by Freight.	TOTAL.

British Columbia.....	1,487,473	148,747	1,487,473	1,487,473	4,413,166
Grand Total.....	\$32,114,833	\$2,213,943	\$30,651,411	\$12,580,868	\$77,401,055

In our statement for 1873 we referred to the yield—\$72,258,693—as "undoubtedly the largest, for one year, in the history of the coast." The accuracy of the statement has been questioned, and the yield of 1853 referred to as being greater. Dr. Lundrman, Director of the U. S. Mint, whose information is probably as reliable as may be had, names \$65,000,000 as the amount produced in 1853, and that amount was not exceeded until 1873, which is now exceeded by 1874, and the recent developments on the Comstock lode justify the belief that the total product for 1875 will approximate \$80,000,000. Yours truly, Jno. J. Valentine, General Superintendent.

Brooks' Improved Process of Distillation.

We take pleasure in laying before our readers an improvement in distillation, which, the inventor, Mr. Robert C. Brooks, of this city, has just patented through the MINING AND SCIENTIFIC PRESS Patent Agency. Before describing the process we will state that Mr. Brooks is a practical distiller, of about thirty years' experience, the last ten years of that time having been expended in completing the improvements which he has just secured by patent. By the new process and improved apparatus the inventor claims to produce alcoholic spirits directly from the still, and by a single distillation, which are absolutely free from fusil oil. We have seen the reports of several of our best chemists, who have analyzed the products of Mr. Brooks' process and which verified his claims to purity and the absence of fusil oil. It is held by many persons that whiskey without fusil oil would be of no value, in fact that it would not be whiskey, but alcohol. This error of opinion arises from the fact that fusil oil, or amylic acid, as it is chemically known, is erroneously supposed by many persons, and even in some of our standard books, to be defined as the oil of grain, oil of potato, etc. Mr. Brooks has discovered, and his experiments have proven, that the essential oil of grain is an entirely separate product, which vaporizes below, or at about the boiling point of water, 212° Fahr., while fusil oil requires a temperature of 280° to be converted into a vapor. This would therefore spoil such an argument. All the volatile products which are obtained from wort, volatilize below the boiling point of water, except fusil oil, and between the boiling point of these two products there is a difference or space of temperature of about 70 degrees. Mr. Brooks takes advantage of this difference or space of temperature to prevent the volatilization of the fusil oil and leave it in the spent wort, and to do this he has invented an improved distilling apparatus which he has also secured by letters patent. This apparatus is so constructed that it is impossible to obtain a temperature in the upper chamber of the still exceeding the boiling point of water or 212° Fahr. Consequently we can only convert to vapor those products of the wort which volatilize at a point below that temperature, thus leaving the fusil oil and a large portion of the water in the wort. The ether which is first volatilized, is condensed and withdrawn entirely from the still before the alcoholic product begins to vaporize so that the subsequent operation proceeds without hindrance.

Mr. Brooks calls his still an automatic pulsating still, because when it is at work its operation is automatically intermittent, thus producing a pulsation as the products of different specific gravities pass up into the condenser.

We cannot spare the space in which to describe the complete construction and operation of this improved apparatus, and to attempt to give the reader a full understanding of the claims of the inventor, without such description would be folly. We will, however, attempt to show the importance of the invention and explain the theory upon which it is based.

Wort, which is the fermented solution from which spirits are obtained contains four volatile products which vaporize as follows, (Fahr): ether, 173°; alcohol, 188°; water, 212° and fusil oil, 269°. It will be seen that the water product stands between the alcohol and fusil oil, giving a clear space of 81° Fahr. of temperature between the desirable and undesirable products.

In Mr. Brooks' apparatus he employs a condensing and separating vessel between the upper chamber of the still and the main condenser through which a constant stream of cold water is made to pass, and this vessel receiving the vapors of ether which first pass from the still condenses them without allowing them to pass into the worm of the still. The condensed ether is then withdrawn entirely from the still before the next product (alcohol) enters the vessel. The condensation of the ether raises the temperature of the vessel so that the alcoholic vapors will pass over into the worm and to the main condenser before it is condensed.

Meers, Van Winkle & Brooks the proprietors of this patent have a large still in practical operation at School House station, near this city, with which they have proven beyond a doubt that the result of their process is all that is claimed for it.

As is usually remarked in such cases "the greatest wonder is that distillers have been so long seeking for some method or process for freeing spirits from fusil oil without discovering this simple common-sense plan. Frequently the very thing we seek for lies just at our doors while we explore the country in a vain search for it. The rationale of the process comprises nothing that is not familiar to the chemist. It only required that this and that be put together and a practical means of carrying out the plan devised to produce the long looked for result. We shall speak again of this invention as it is developed.

The Jersey mines are attracting a good share of attention. The mines are situated 50 miles in a direction west of north from Battle Mountain, Nev. But little work has been done, except on the Trimble mine.

The Centennial Exhibition Building, Philadelphia, 1876.

We will suppose that all the readers of the RURAL PRESS have already heard of the manner in which it is proposed to celebrate the hundredth anniversary of the existence of the United States as an independent nation, and of the magnificent building in which all the nations of the earth are invited to exhibit their products. Of this building we give a splendid illustration, as also of the Art Gallery, which it is expected will contain some of the most distinguished works of painting and sculpture to be found in Europe or America. The whole structure will be supported on piers of massive masonry, while the superstructure will consist of wrought iron columns with roof trusses of the same material. The columns will be of rolled channel bars with plates riveted to the flanges, while the roof trusses are straight rafters with struts and tie bars. The building in shape, a parallelogram, extends east and west 1,688 feet, and north and south 464 feet. Should necessity arise, these dimensions will be increased.

The Principal Buildings

Are the Main Building, the Art Gallery, the Machinery Hall, the Agricultural and the Horticultural Halls. In the aggregate they cover a floor space of about 46 acres.

The larger portion of the structure is one story in height, and shows the main cornice upon the outside at 45 feet above the ground, the interior height being 70 feet. At the centre of the longer sides are projections 416 feet in length, and in the centre of the shorter sides or ends of the building are projections 216 feet in length. In these projections, in the centre of the four sides, are located the main entrances, which are provided with arcades upon the ground floor, and central facades extending to the height of 90 feet.

Upon the corners of the building there are four towers 75 feet in height, and between the towers and the central projections or entrances, there is a lower roof introduced showing a cornice 24 feet above the ground.

In order to obtain a central feature for the building as a whole, the roof over the central part, for 184 feet square, has been raised above the surrounding portion, and four towers, 48 feet square, rising to 120 feet in height, have been introduced at the corners of the elevated roof.

The areas covered are as follows:

Ground Floor.....	872,320 sq. feet	20.02 acres.
Upper Floors in projections, 37,344 "		.85 "
" " in towers	26,344 "	.60 "
Total.....	936,008 "	21.47 "

Ground Plan.

The general arrangement of the ground plan shows a central avenue or nave 120 feet in width, and extending 1,832 feet in length. This is the longest avenue of that width ever introduced into an Exhibition Building. On either side of this nave there is an avenue 100 feet by 1,832 feet in length. Between the nave and side avenues are aisles 48 feet wide, and on the outer sides of the building smaller aisles 24 feet in width.

In order to break the great length of the roof lines, three cross avenues or transepts have been introduced of the same widths and in the same relative positions to each other as the nave and avenues running lengthwise, viz: a central transept 120 feet in width by 416 feet in length, with one on either side of 100 feet by 416 feet, and aisles between of 48 feet.

The intersections of these avenues and transepts in the central portion of the building result in dividing the ground floor into nine open spaces free from supporting columns, and covering in the aggregate an area of 416 feet square. Four of these spaces are 100 feet square, four 100 feet by 120 feet, and the central space or pavilion 120 feet square. The intersections of the 43 foot aisles produce four interior courts 48 feet square, one at each corner of the central space.

The main promenades through the nave and central transept are each 30 feet in width, and those through the center of the side avenues and transepts 15 feet each. All other walks are 10 feet wide, and lead at either end to exit doors.

The Art Gallery.

Is located on a line parallel with and northward of the Main Exhibition Building.

It is on the most commanding portion of great Lansdowne Plateau and looks southward over the city.

It is elevated on a terrace six feet above the general level of the plateau—the plateau itself being an eminence 116 feet above the surface of the Schuylkill River.

The entire structure is in the modern renaissance. The materials are Granite, Glass and Iron. No Wood is used in the construction, and the building is thoroughly fireproof. The structure is 365 feet in length, 210 feet in width, and 59 feet in height over a spacious basement 12 feet in height, surrounded by a dome.

The dome rises from the center of the structure to the height of 150 feet from the ground. It is of Glass and Iron and of a unique design; it terminates in a colossal bell—from which the figure of Columbia rises with protecting hands.

A figure of colossal size stands at each corner

of the base of the dome. These figures typify the four quarters of the globe.

The main entrance opens on a hall 82 feet long, 60 feet wide, and 53 feet high, decorated in the modern renaissance style; on the farther side of this hall, three doorways, each 16 feet wide and 25 feet high, open into the center hall; this hall is 83 feet square, the ceiling

14 feet wide, which opens on its north line into a series of private rooms, thirteen in number, designed for studios and smaller exhibition rooms.

All the galleries and central hall are lighted from above; the pavilions and studios are lighted from the sides. The pavilions and central hall are designed especially for exhibitions of sculpture. There will be

Dept. VII. Apparatus and methods for the increase and diffusion of knowledge.

Dept. VIII. Engineering, public works, architecture.

Dept. IX. Plastic and graphic arts.

Dept. X. Objects illustrating efforts for the improvement of the physical, intellectual and moral condition of man.

In this connection we may mention that the *San Francisco Journal of Commerce* has applied for a space 50x50, wherein to represent raw materials and staples produced on the Pacific Coast.

How the Work Progresses.

Philadelphia papers represent the work as progressing favorably. The contractor is trying to

of the dome rising over it 80 feet in height. From its east and west sides extend the galleries, each 98 feet long, 48 feet wide, and 35 feet in height. These galleries admit of temporary divisions for the more advantageous display of paint-

Ten Departments

Of classification, divided into one hundred and nine groups, subdivided into one thousand and ninety-nine classes. The departments of classification will be as follows:

The Pacific Coast Commissioners

With their alternates are as follows:

California—J Dunbar Creigh, San Francisco; alternate, Benj. P Kooser, Santa Cruz. Oregon—J W Burke, Baker City; alternate, A J Dittfur,

place the Memorial Hall under temporary cover, to allow work inside during the winter. The interior walls have reached a height of about fifty feet, or above the span of the arches which form the entrance to the magnificent vestibule. On

THE CENTENNIAL ART GALLERY.

ings. The center hall and galleries form "one grand hall 287 feet long and 85 feet wide, capable of holding eight thousand persons, nearly vice the dimensions of the largest hall in the country. From the two galleries, doorways open into two smaller galleries, 28 feet wide and 89 feet long. These open north and south into private apartments which connect with the pavilion rooms, forming two side galleries 210 feet long. Along the whole length of the north side of the main galleries and central hall extends a corridor

Dept. I. Materials in their unwrought condition—mineral, vegetable and animal.

Dept. II. Materials and manufactures the result of extractive or combining processes.

Dept. III. Textile and felted fabrics—apparel, costumes and ornaments for the person.

Dept. IV. Furniture and manufactures of general use in construction and in dwellings.

Dept. V. Tools, implements, machines and processes.

Dept. VI. Motors and transportation,

Portland, Nevada—W W McCoy, Eureka; alternate, Jas W Haines, Genoa. Utah—John H Wickiier, Salt Lake City; alternate, Oscar G Sawyer, Salt Lake City. Idaho—Thos Donaldson, Boise City; alternate, Christopher W Moore, Boise City. Montana—W H Claggett, Deer Lodge City; alternate, Patrick A Largey, Virginia City. Washington Territory—Elwood Evans, Olympia; alternate, Alexander S Abernethy, Cowlitz county. Arizona—Hon. Richard C McCormick, D. C.; alternate, John Walson, Tucson.

the exterior walls all the rough granite up to the water-table is in place, and on the southwest corner the masons have laid a considerable quantity of the fine Richmond granite which is to form the superstructure. Enough is now laid at the Memorial Hall to indicate its beauty and demonstrate the imposing character of the edifice. The granite at the southwest corner is about six feet above the water-table. It is backed with brick, laid in cement, the entire wall being five feet thick and is to be continued to the full height.

South Mountain.

This camp which, until recently, has been wholly unknown to everybody with the exception of a few, is now commencing to attract the attention of prospectors, both in Idaho and Nevada, and is destined to become a large and prosperous mining camp at no far distant day.

The South Mountain

Consolidated Mining company, an organization which numbers among its members several wealthy and influential citizens, not only of Owyhee, but also of San Francisco, has employed a large number of men all the fall in the work of extracting the precious metal from the bowels of mother earth, and consequently has a large amount of ore on hand which will yield \$300 to \$500 per ton. They have recently constructed a large furnace for the purpose of smelting the ores of that camp, and have appointed Sam Wessels, a skillful metallurgist, and one of the original locators of the camp, to superintend the works.

The Furnace is now Working to a Charm, And surpasses the most sanguine expectations of those who always had the utmost confidence in its ultimate success. We understand that it is the intention of the company to erect another furnace next spring. We, in common with hundreds of others who take an interest in the future welfare of Owyhee county, sincerely hope that success will crown their efforts, and that they will succeed in every enterprise which they may undertake; for it depends on the success of the persons who have money invested in South Mountain for the success of every person in Owyhee county. Comparatively speaking, the people of South Mountain have, until quite recently, been isolated, they being almost entirely cut off from any connection with the outside world; but now that Platte River, the energetic superintendent of the Atlantic, Pacific, Nevada and Northern Telegraph Line, has extended his line of telegraph from

Silver City to South Mountain,

The people of that isolated burg can no longer be wholly ignorant of what is transpiring around them. Next spring, when the company commences mining operations in good earnest and the permanency and value of the mine become established, good wagon-roads will undoubtedly be constructed from various points, or no doubt some enterprising man will run a regular line of stages from Silver City to South Mountain. South Mountain City, formerly Bullion City, is located in close proximity to Silver City, both camps not being over 30 miles distant from each other. This circumstance cannot fail to be of great benefit, financially, to the people of both camps, inasmuch as they can go from one camp to another in a day's ride. When we take all our natural advantages into consideration we are led to the conclusion that there is, as we have already stated, a bright future in store for the people of Owyhee county. We think that when the sun of another summer shall make its appearance that Silver City and South Mountain combined will

Employ at Least 2,000 Men,

And we furthermore think that the day is not far distant when Owyhee county will prove itself to be one of the richest and most extensive gold and silver producing districts on the Pacific Coast.—*Cor. Bedrock Democrat.*

New York Hill Mine.

This mine is owned by an incorporated company, whose principal place of business is at San Francisco. The most of the stock of the company is owned by the estate of the late A. Delano. The mine is situated about two miles and a half south of Grass Valley. It employs 45 miners, and is paying, at the present time, \$2.50 per day to each miner. It is said that at an early day, and as soon as the mine has something better of surroundings, full wages will be paid. The cost of drifting is \$15 per foot, and stopping costs \$15 per ton, making the extraction of ore cost \$15 per ton. Milling the ore costs \$4.50 per ton, and the work has been so far done at the Larimer mill. The number of tons worked during the year has been about 500, and the average yield has been not less than \$50 per ton, making a total haulion yield of \$25,000. The location is about 3,000 feet in length, and the ledge runs northeast and southwest, dipping to the northeast. The length of pay zone, so far as explored is 1,400 feet, with an average thickness of 2½ feet. The country rock, as far as explored, consists of greenstone and slate. The ledge is worked through a tunnel which has now a total length of 750 feet. There are two drifts opened from the tunnel. There are 400 feet of backs above the tunnel workings. On the ledge there is a shaft, not used at present, but which is available at any time for working, of the depth of 700 feet. The total length of drifts in the mine is 500 feet. Mr. Joseph Snyder is the Superintendent of the mine.—*Grass Valley Union.*

GOLD IN SONORA.—There is a report in Tucson, Arizona, regarding a rich gold mine in Sonora, on the San Miguel river, near Ures. Some lumps, worth \$60, which were obtained by washing with a wooden bowl, have been exhibited here. The claims cover a mountain two miles square, more or less, and gold is found on the entire surface. High up on the mountain a great deal of mining was done a century ago and continued down to the point where the vein turned to sulphurets of silver, which they could not work.

Geological Puzzle.

Prof. R. Weiser, of Georgetown, Colorado, contributes the following to the *Journal of Science and Arts*: Geologists have been not a little perplexed with the frozen rocks found in some of our silver mines in Clear Creek county, Colorado. I will first give a statement of the facts in the case, and then a theory for their explanation. There is a silver mine high up on McClellan mountain called the Stevens mine. The altitude of this mine is 12,500 feet. At the depth of from 60 to 200 feet, the crevice matter, consisting of silices, calcite and ore, together with the surrounding wall-rocks, is found to be in a solid, frozen mass. McClellan mountain is one of the highest eastern spurs of the Snowy range; it has the form of a horseshoe, with a bold escarpment of feldspathic rock, near 2,000 feet high, which in some places is nearly perpendicular. The Stevens mine is situated in the southwestern head of the great horseshoe; it opens from the north-western. A tunnel is driven into the mountain on the lode, where the rock is almost perpendicular. Nothing unusual occurred until a distance of some 80 or 90 feet was made; and then the frozen territory was reached, and it has continued for over 200 feet. There are no indications of a thaw, summer or winter; the whole frozen territory is surrounded by hard, massive rock, and the lode itself is as hard and solid as the rock. The miners being unable to excavate the frozen material by pick or drill, to get out the ore, (for it is a rich lode, running argentiferous galena from 5 to 1,200 ounces to the ton), found the only way was to kindle a large wood fire at night against the back end of the tunnel, and thus thaw the frozen material, and in the morning take out the disintegrated ore. This has been the mode of mining for more than two years. The tunnel is over 200 feet deep, and there is no diminution of the frost; it seems to be rather increasing. There is, so far as we can see, no opening or channel through which the frost could possibly have reached such a depth from the surface. There are other mines in the same vicinity in a like frozen state.

From what we know of the depth to which frost usually penetrates into the earth, it does not appear probable that it could have reached the depth of 200 feet through the solid rock in the Stevens mine, nor even through the crevice matter of the lode, which as we have stated, is as hard as the rock itself. The idea, then, of the frost reaching such a depth from the outside, being utterly untenable, I can do no other way than to fall back upon the Glacial era of the Quaternary. Evidences of the Glacial period are found all over the Rocky mountains. Just above the Stevens mine there are the remains of a moraine nearly a mile long, and half a mile wide. The debris of this moraine consists of small square and angular stones, clearly showing that they have not come from any great distance. And just over the range, on the Pacific slope, there are the remains of the largest moraine I have ever seen, consisting of feldspathic boulders of immense size. I conclude, therefore, that it was during that period of intense cold that the frost penetrated so far down into these rocks, and that it has been there ever since, and bids fair to remain for a long time to come.

Opening Outside Mines.

Our brother editors here in Virginia are splitting hairs about something which we suspect they would not disagree about for a moment if they would sit down and exchange ideas instead of firing at long range at each other, as they are now doing. One wants men of small means to explore Eastern Nevada and open up new enterprises. The other reports "Oh, yes, give up four dollars a day and go to Eastern Nevada and starve." Now both are right and both are wrong. It would be foolish to leave a means of making a comfortable livelihood to go on any uncertainty. But if several men, each with a surplus of several thousand dollars, choose to make up a purse with a part of their hoarded means to open some as yet unexplored field, there can be no objection; on the other hand, there is every reason to encourage such a course, for it is by such means that new mines are developed and new districts opened. There are two reasons why so many mining enterprises are failures. They are generally, first, lack of judgment, and secondly, lack of means. One-half the work done on mines in this State is dead work, because men followed their hopes after their leads were lost. In this we are not talking of the chronic prospector, whose feet have climbed every hill in the State, and who, were he to come upon a Potosi to day, would trade it to-morrow for a mustang and a sack of flour to follow again his dream. Such mortals need a hook of their own to describe them as they are. But, with careful business men, the easiest thing in the world is to be mistaken about a mine or the best way to explore it. Hence, this work should be approached with the greatest care, and never started until capital sufficient to a little more than do the expected work is secured. For men of small capital there is no way to go to work except by means of joint-stock companies or incorporations. The proof of this is, that notwithstanding thousands have tried, the really successful mining enterprises in the State outside of Storey county can be counted on one's fingers, and that after 12 years of toil. But if a company of men will each put in his quota, then secure a property which a man of experience is sure will justify the work, and go

to work practically and honestly, the probability is that they will more certainly secure a fortune than by wandering about these streets and betting on a guess.—*Virginia Enterprise.*

COAL BORER.—The Nanaimo Free Press says: The Vancouver Coal company are importing from England a Diamond Rock Boring machine which is calculated to work wonders in piercing the hard rock of the country hereabout. A machine similar to the one the company have obtained has been in operation at Middleboro'-on-Tees, and it bored a hole 690 feet in sandstone in the short space of three months, including the time occupied in fixing the engine and apparatus. By the Diamond Drill samples of the strata passed through are brought up in the form of cylindrical cores. Such a method must be invaluable, securing, as it does, solid specimens of the rocks and minerals, which cannot only be judged by appearance in their natural condition, but may be analyzed without risk of error by mixture with contiguous rocks, as in the old system of boring. The speed of boring with the new patent drill is considered to be from six to twelve times quicker than by the ordinary way.

NEW SHAFT.—A new shaft through which to work that portion of the great honauza lying in the Consolidated Virginia and California mines was started a few days since. The shaft will be of the largest size, and will be pushed downward as rapidly as possible. Its location is 1,040 feet northward from the main shaft of the Consolidated Virginia mine, and it will be known as "C and C" shaft. As soon as it shall have been completed, hoisting apparatus of the most improved pattern will be placed upon the surface and everything prepared to bring the great ore body below to daylight. And what with this and other improvements both in contemplation and in actual progress at our mines and the building of business and dwelling houses on every hand about us, a most prosperous season for builders and mechanics generally seems about dawning, or, rather, to have already dawned.

THE Cerro Gordo furnace men, says the Inyo Independent, since the establishment of the smelting industry have been diligently prosecuting experiments with a view to ascertaining exactly how to construct a furnace that will wear the longest and produce the best results. The annual increase of hullion testifies to their success; but of late some improvements have been introduced which seem likely to supersede all the old styles. Belshaw has in very successful operation what is known as a "water jacket," which is simply a double iron boiler, the inner one lined with fire clay, and between them is the water. Beaudry proposes substituting a species of soapstone, found some five miles south of the town, for the molded fire-clay brick hitherto in use. The stone has been used in "patching," and found to stand the intense heat for a long time.

FROM ALTURAS.—Hon. S. B. Dilly and lady have arrived from Rocky Bar; the latter will remain with her friends through the winter, while Mr. D. will return after a short visit. The news which Mr. Dilly brings from Alturas shows a healthy state of affairs in that camp. He says they have a fair quantity of supplies, and the freight now on the road will get in, and they will have an abundance. There don't appear to be any idle men in the camp, as has usually been the case during the winter. Dr. Newton, Superintendent of the Pittsburg company Col. Ward of the Valley company, Mr. Cavanaugh, of the Buffalo company, Mr. Thomas, of the Wide West company and Jake Reaser & Co., who own the Vishnu and have also leased the mines of Wahl & Bros., are each working about ten men, and the Pittsburg, Valley and Wide West mills are running nearly all the time night and day with good results.—*Idaho Statesman.*

From an Inventor.

The following letter, which was recently received from an old client of Dewey & Co., now residing in one of the Eastern States, speaks for itself:

GENTLEMEN: It was through your house that I secured my first patent, and although I have since done business here in the Atlantic States with the ablest patent solicitors—gentlemen who have done me justice—yet I have often regretted that you were too far off to advise with me in my cases. It has taken a longer time with every patent I have taken out since I left California and came East, than in the cases you prepared for me in San Francisco, which is certainly very creditable to you.

By the way, one of my patents has passed the ordeal which is the essential test of a patent's value. I mean that of a trial in the courts, and it stood the hatching of one of the best lawyers in the country. The specifications and claims were completely made out and there was a perfect comprehension of its principle during the trial. Since giving it this test we thought that we would make it even stronger, if possible, and submitted it to one of the best patent solicitors for advice. After a careful examination of the case he advised us to let it alone as it stood, saying that whoever made up those papers understood their business. I then informed him that they were drawn up by Dewey & Co., of San Francisco, and he replied that he knew you very well by reputation. Very truly yours,

L. L. SAWYER.

Meriden, Conn., May 16, 1874.

TRUCKEE, CAL., July 10, 1874.

MESSES, DEWEY & CO.—Gentlemen: My patent is just received, and is entirely satisfactory. Permit me to tender you my sincerest thanks for the care and attention, the promptness and interest you have displayed in managing my affairs. Gratefully yours,

C. F. McGLASHAN,

DEWEY & CO.

American & Foreign Patent Agents,

OFFICE, 224 SANSOME STREET, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent révisions taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Victoria, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Grenada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule prices for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) sooner than any other agents.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing them to the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applications which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents, or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency. The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more directly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by the extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

DEWEY & CO.,

United States and Foreign Patent Agents, publishers Mining and Scientific Press and the Pacific Rural Press, 224 Sansome St., S. F.

The Mining and Scientific Press--Ever Onward.

Our careful system of compiling, judiciously condensing, and conveniently arranging into regular departments, has been heartily endorsed. It renders the paper worth a score to readers, who can and handily that which interests them most.

The weekly issues of the Press will obtain reliable

Information for Practical Miners,

Treating on the Opening of Mines; Mining of Ores; Milling of Ores; Smelting of Ores; Separation and Roasting of Ores; Amalgamation; Saving of Gold and all precious Metals; New Processes of Metallurgy; New Discoveries of Mines; Mining Engineering and Hydraulics.

For Inventors, Mechanics and Manufacturers.

All new and important developments in Scientific and Mechanical Progress; Patents and Inventions of the Pacific States; Progress of Home Industries; Hints for Local Manufacturers; Illustrations of New Machinery; Reports of Popular Scientific and Industrial Lectures.

Our Mining Summary

Gives the progress of mining work from week to week in the various counties and districts throughout the principal mining regions of the United States, arranged in alphabetical order. It is the most extensive record of mining operations published in the world. It affords the intelligent miner a rare opportunity to know and profit by the work and experience of his neighbors. Miners have few sources of practical information in their calling, and should embrace every reliable means for improvement. Mining Operators and Shareholders, at home and abroad, weekly examine our Summary with increased interest and profit.

Our "Domestic Economy"

Embraces new and important facts which should be known in every cabin and household. Short and interesting—the articles under this heading are freely read and practiced with profit and improvement to the reader.

The Press is not strictly a "paper for professional scientific men," but rather a

Liberal and Popular Scientific Journal,

Well calculated to make, practically scientific men from uneducated masses. This is our stronghold for accomplishing good. Plain, correct and pleasing language, easily comprehended by all, confined mostly to short articles, is our endeavor.

For Self-Improvement,

Every issue of the Press abounds with articles of an elevating character, to stimulate the higher virtues and secure and progressive intellects of both men and women.

Hundreds of Dollars

are oftentimes saved to the readers of this paper by a single hint or article of information in its columns; such instances have been repeatedly reported to the editors and proprietors during their long connection with the Press. Our paper presents

The New and Novel Developments

in the progress of this comparatively new section of the Union (but recently settled and now rapidly increasing with a population of the most intelligent and venturesome people, attracted from nearly every quarter and climes on the globe), enable us, with due enterprise, to display vigor and freshness in our columns not met with in similar journals elsewhere. The same circumstances also render such a paper more especially valuable to its readers in a new and, to a certain measure, untried field, where the best methods and processes of industry are not so well established or traditionally known as in older communities. Published experiences often save costly experiments and disastrous results.

A Great Variety of Industrial Information,

in brief and fresh form, suited to the wants and tastes of the readers of this coast, which is not obtainable otherwise so timely, or in so cheap and convenient form. As an industrial publication, meeting the wants of so many kindred industries, this journal stands pre-eminent and without a precedent.

Subscriptions payable in advance—\$4 per annum Single copies, post paid, 10 cents. Address

Ayer's Cherry Pectoral,
For Diseases of the Throat and Lungs, such as Coughs, Colds, Whooping Cough, Bronchitis, Asthma and Consumption.

The few compositions, which have won the confidence of mankind and become household words, among not only one, but many nations, must have extraordinary virtues. Perhaps no one ever secured so wide a reputation, or maintained it so long, as AYER'S CHERRY PECTORAL. It has been known to the public about forty years, by a long continued series of marvelous cures, that have won for it a confidence in its virtues, never equalled by any other medicine. It still makes the most effectual cures of Coughs, Colds, Consumption, that can be made by medical skill. Indeed the CHERRY PECTORAL has really robbed these dangerous diseases of their terrors, to a great extent, and given a feeling of immunity from their fatal effects, that is well founded, if the remedy be taken in season. Every family should have it in their closet for the remedy and prompt relief of its members. Sickness, suffering and even life is saved by this timely protection. The prudent should not neglect it, and the wise will not. Keep it by you for the protection it affords by its timely use in sudden attacks.

STEAM ENGINES AND BOILERS
Of all sizes—from 2 to 60-Horse power. Also, Quartz Mills, Mining Pumps, Hoisting Machinery, Shafting, Iron Tanks, etc. For sale at the lowest prices by
10v27-1f J. HENDY, No. 32 Fremont Street.

New Inventions!
Of real merit, if brought plainly before the public when fresh, are most likely to become profitable to the patentee. For this reason, patentees (of worthy devices) should have the best of Engravings Made, and published in the Press. Superior Engravings Made, at reasonable rates, by artists in this office. bp-1f

Machinery.

N. Seibert's Eureka Lubricators.

THE HIGHEST PREMIUM

Awarded by the Mechanics' Institute Fair, San Francisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers to be superior to any they have ever used; feed constantly by pressure of condensed water, supplied by pipe A, regulated under the oil by valve J, and forced out through check valve and pipe B into the steam pipe C; it then becomes greasy steam, passes to all the valves and cylinder at every stroke of the engine; glass tube I indicates amount used per hour. Packing on rods and stems lasts longer, and the rings on the piston will not corrode. One pint of oil will last from three to six days, according to speed and size of engine; I, sliding gauge; K, valve to shut off when engine stops; H, F, valves to shut off in case of frost; steam does not enter the cup; it is always cool; warranted to give satisfaction. Patented February 14, 1871. Made by California Brass Works, 125 First street, S. F. 24v23

BALL'S

SWEEPING DREDGE,

A NEW AND VALUABLE

CALIFORNIA INVENTION,

Has been very lately well proven by performing a job of dredging at the mouth of San Antonio Creek, at Oakland, Cal.

There is but this one machine that has ever had these improvements employed. It is an old machine, formerly built for another device, and is unfavorably constructed for Ball's improvements; yet this first temporary experimental machine has filled a scow of eighty-five cubic yards in sixteen minutes in unfavorable digging. For durability, digging hard material and fast work, it has a reputation (supported by leading engineers) as having no equal.

Testimonials and references will be given on application to the inventor, who is the sole owner of patents (excepting having made an assignment of the one machine now belonging to the Central Pacific Railroad Company) Having resolved not to sell any rights unless upon a basis of actual work performed by a machine built by myself for the purpose of fairly establishing the worth of the invention, I therefore offer to sell machines or rights on the following plan, which is warranting the capacity of the machine by actual work:

I will enter into an agreement with any responsible party to build and sell a machine, scows and tender, all complete, and right of all my improvements in dredging machines throughout the Pacific Coast for \$20,000, warranting the machine to dredge six cubic yards per minute (to fill a scow at that rate). \$20,000 will but little more than pay the cost of building the machine, scows, etc., all complete; therefore I am proposing to ask nothing for my patents unless my machine dredges more than six cubic yards per minute. But it shall be further agreed that in case (at a fair trial) to be made within a stated time) the machine shall fill a scow at the rate of more than six cubic yards per minute, then \$10,000 shall be added to the price above stated for each and every such additional cubic yard thus dredged per minute, and for additional fractions of a cubic yard thus dredged in the same ratio the \$10,000 is to be added to said price above stated.

I will sell any other Territorial or State rights (either United States or Foreign) upon the same plan and at a lower price proportionately than the rights for the Pacific Coast.

I will sell a single machine with scows and all complete, and right to use the same in a limited territory, for \$20,000 on the same plan as above stated, but will add only \$2,000 to each additional yard over the six cubic yards per minute. Each machine is not to employ more than two 10x20 inch engines.

Payments to be made in U. S. gold coin on delivery of machine, as may be indicated by agreement.

Address, **JOHN A. BALL,**

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits. They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:

The pan being filled, the motion of the miller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Sellers made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill-men are invited to examine these pans and sellers for themselves, at the office, 229 Fremont Street, San Francisco.

The United States of Colombia.

We had a conversation this week with a gentleman who has recently returned from the United States of Colombia. He speaks hopefully of the prospects of the Americans who are opening up the gravel mines in the interior. The gravel mines owned by Weaver & Co. are 30 miles from Barbacoas, on the Nyambas river. They have plenty of water for hydraulic and have one monitor at work, employing seven or eight men. The other mines are 15 or 20 miles above Barbacoas, and a company of San Franciscans expect to take down the requisite machinery to work them. There are some five or six companies, some getting their claims in order to work. Brown & Gentry have a large estate on which one monitor is at work, and three or four more will be added. These mines are on the Yacura river. The gravel is pretty good, and where water can be had, will pay well. Some of the gravel will pay handsomely. Labor is pretty cheap and men can be employed for from 37½ cents to \$1 per day and board. Weaver & Co. pay 37½ cents and board for common men and \$1 per day and board for drifters. Most of the companies have just started in and have done little as yet. On all the large estates the natives mine in a rude way for a share of the profits. All the mines pay well where the water can be brought on; some, however, have very little water.

The gentleman who gave us this information brought up with him a number of articles from the country which are interesting. He showed us the Brazil nuts in the cone-shaped cover in which they grew. Also, some "milk" of the India-rubber tree which grows up in the mountains. He brought some coffee from the Cauca valley, which is of excellent quality; an American there has a plantation of 70,000 coffee trees which yield an average of 3½ pounds to a tree. The coffee grows there plentifully and his trees are of such a growth that he is continually gathering, as some trees are in while others are out of season. The owner of this plantation also has 160 acres in sugar cane. This sugar cane takes 15 months to mature after each cutting, the roots of course remaining. We were shown also from the Cauca valley, some excellent wild cotton. This valley is about 48 miles from the coast on an air line, and has an elevation of 3,000 feet. The cotton has a first-rate fibre. It has never been cultivated there to any account. Our informant, a practical cotton grower and manufacturer, thinks the Cauca valley the best locality for an investment for a cotton mill there is in the world. The natives would cultivate the cotton if there was a demand for the product. A small cotton mill of 50 looms would do exceedingly well, and our informant thinks it would clear \$600 per day right along. Common cotton cloth, without print, could be sold there in quantities at 20 cents per yard. There is plenty of water power to run a mill and plenty of ground to be had to cultivate the cotton, and the product would meet with ready sale. We should judge from the figures shown us, that this favorable opportunity will not long lie idle, for some enterprising American will take it up. We were shown among other things several of the "ivory nuts" grown there, from which small articles are made. Also a species of cloth, resembling the Kapa cloth of the South Sea islands, made from the inner bark of a tree. It is tough and thick, and in a cold climate would do very well for clothing. Some of the wood grown there is very hard and fine grained.

There are no roads in the mining part of the country, except the trail from Barbacoas, all the travel being done in canoes or on the backs of Indians. The trail to the mines has been traveled for 300 years, and worn down in places from ten to forty feet. The government is now building a road from Barbacoas to the interior 80 miles long, 20 miles of it being finished, and 200 men being at work on the rest. To the upper mines they go by the trail. The road will give access to the mines so that horses can be used. To the Cauca valley there is a trail or small road, which is pretty good for this country.

A ledge of silver ore has lately been discovered in the State of Cauca, in the foothills, which assays \$50 per ton in silver and \$6 in gold.

THE MECHANICS' INSTITUTE FAIR.—The Board of Trustees of the Mechanics' Institute announce the opening of the next Mechanics' Fair for the middle of August next. They have already commenced making arrangements for it. It is intended to make the horticultural display one of the most marked features of the next exhibition. The garden, which was arranged last year by the Bay District Agricultural Society, will be flooded over and used for other purposes. The lot adjoining the pavilion on the east, which has a frontage of 170 feet on Mission street and runs back to the boiler house, a distance of about 300 feet, will be laid out with walks, avenues, shady groves and fountains.

THE PARTNERSHIP OF CONROY, O'CONNOR & CO., the well known hardware dealers in this city, has expired by limitation and the entire interests of the firm have been purchased by W. F. Dunham, E. W. Playter, B. Hayden, W. L. McCormick and A. Carrigan, who have been clerks and partners in the establishment for 15 years. The new firm is known as Dunham, Carrigan & Co.

General News Items.

CONGRESS.—A large amount of work is in preparation for Congress, during the recess and upon the reassembling there will be a rush of business as well as great political activity. The Arkansas Investigation Committee's report will then be forthcoming; to be followed soon after by the reports of several select committees now in various sections of the South and the Civil Rights bill must be acted upon shortly, as it is at the top of the pile on the Speaker's table. The new finance bill comes up by special order on January 7th. The Senate Census Committee will make their report on cheap transportation. The Committee on Appropriations expect to have the remaining Appropriation bills completed by the time of re-assembling, and their consideration will be pressed upon the House forthwith; indeed, all the most important subjects are in such a shape as to be presented almost simultaneously for action.

THE SPANISH REVOLUTION.—A very sudden termination has been given to the Spanish Republic, by the proclamation of the son of ex-Queen Isabella, as King of Spain, under such circumstances as secured his immediate recognition by almost the entire army and navy and a large majority of the leading civilians throughout the country. Even Castelar, it is understood, with other leading Republicans, gives in his adherence. There seems to have been a very general impression that nothing else could restore that distracted country to tranquility. The European Government appear to be very well satisfied with the result, and will recognize the accession of the young Prince of Asturias to power, as soon as he arrives and assumes the reigns of Government, which will be in a few days. The Prince is now about 16 years of age, but well educated and possessing a full understanding of the responsibility he is assuming.

TERRIBLE EXPLOSION.—Two miners were instantly killed in the Suto tunnel on the 30th ult., and a number of others seriously injured—one fatally. The accident was of quite a singular nature, and should be studied and borne in mind by all persons using nitro-glycerine. It happened at the time of changing shifts, and a blast was about to be exploded in the face, or header, of the tunnel. The men retreated back about six hundred feet, where the battery used in exploding blast was situated. Several boxes of giant powder had been left near the battery, and when the blast in the header was touched off, the powder near the battery also exploded, by what means is not fully understood.

THE PACIFIC MAIL INVESTIGATION makes slow progress. The testimony thus far looks bad for somebody, and especially for Mr. Congressional ex-Postmaster King. A Washington special says: If the testimony given in New York concerning Mr. King proves true this gentleman has subjected himself to the punishment attached to perjury, since in his examination before the committee in the last Congress, he testified then that he did not receive one dollar, either directly or indirectly, in behalf of the subsidy schemes. Efforts are evidently being made on the part of certain persons to cover things up.

THROWN FROM A WAGON AND KILLED.—The body of A. Roscoe, a farmer, about 70 years of age, residing about a mile from Sheridan, Placer county, was found Friday morning on the plains, north of the Rancho de Passa. The jury of inquest decided that he was killed by being thrown from his wagon.

GARIBALDI.—After all that has been said and done Garibaldi cannot be induced, even in his poverty, to accept of aid from any source—either public or private. He has just refunded the substantial aid which the Italian Government offered him, on the plea that that the finances of the Government were suffering.

COLD WEATHER.—Halleck station, east of Elko is said to be the coldest point on the Central Pacific railroad. The mercury went to 9 degrees below zero there a few days since. Considerable floating ice from above was seen in the Yuba river at Marysville, yesterday something unusual in that region.

FIRE IN THE TULE.—During last week the tules on the Sacramento river, directly west of Marysville, were on fire, giving forth lurid flames at night, and clouds of smoke during the day time, when viewed from Sacramento city.

SPONTANEOUS COMBUSTION.—Some wool in the Oregon woolen mill at Portland took fire from spontaneous combustion, last week, out was extinguished before much damage resulted.

THE BEECHER-TILTON CASE.—Five hundred witnesses were subpoenaed for the Beecher-Tilton case which went to trial on Monday. It is said that Beecher received 1,000 calls on New Years.

VASQUEZ.—The trial of this noted bandit commenced on Tuesday last. The law's delay could not be forced any farther.

DEATHS FROM FAMINE.—Accounts from Aelia Minor show that deaths from the famine is increasing, and that many deaths occur daily.

NEW POSTMASTER AT QUINCY.—T. F. Hersey has been appointed postmaster at Quincy.

Industrial Items.

OUR BUILDING INDUSTRIES.—The value of houses erected in this city during the past year cannot be less than five millions of dollars. The total number of workmen employed during the year in the building trade has not averaged less than 3,000, who with their families, etc., represent not less than 10,000 of the city's population. There is no sign of any decrease in the number, as at the present moment not less than 400 houses are in course of construction in various parts of the city, and the incoming year is regarded as likely to be more active for the building business than even the last.

MANUFACTURING of every description is flourishing in this city and State as never before. The mills, the boot and shoe manufactories, the manufactories of case goods, and, in fact, every description of industrial productions are increasing their number of employees. The increase in this direction in this city during the past year has been over 1,000 hands. We are just entering upon a new year with most extraordinary evidences of prosperity.

THE foundries and machine shops in this city were never more busy than now, on account of the demand from the mines for machinery and house work in this city.

ANOTHER PALACE.—Milton S. Latham has made a large purchase of property on the southeast corner of Pine and Jones extending down to Bush street. He means to build a fine city residence there.

THE last spike of the railroad from Saucelito to Tomales was driven on the 29th ult., and the road will soon be open for travel.

MERCEN City is moving for a flinning mill.

THE Nevada Legislature met at Carson on Monday last, was duly organized and listened to the message of Governor Bradley, which is a plain, straightforward document, presenting a most encouraging account of the general condition of the State, particularly in relation to the State finances. The net indebtedness of Nevada is next to nil—aggregating only \$84,164, with a school fund in the treasury amounting in round numbers to \$250,000. The assessed value of real and personal property in the State is \$26,866,605, with a revenue for State and county purposes of \$930,888. The Republican members of both Houses met in convention on Wednesday, and unanimously nominated Mr. Sharon for U. S. Senator, which is equivalent to an election by a large majority over all competitors. Subsequent to the nomination Mr. Sharon received the congratulations of his friends at his rooms in the Ormsby house. The Legislature is now prepared to enter upon the business of the session, which will doubtless be a short and successful one.

IMPROVED CONCENTRATOR.—Mr. John Vincent, familiarly known as the "One-eyed Scissors-grinder," who keeps a stand on nights on the corner of Pine and Kearney streets, besides being a poet and scissors-grinder has also proven himself to be an inventor. He has invented a dry ore concentrator for which he has applied for letters patent, through the MINING AND SCIENTIFIC PRESS Patent Agency. The machine is very ingenious and appears more than ordinarily effective. When Mr. Vincent gets his patent we will favor our readers with a description of his concentrator.

HOT WATER.—The water encountered in the main east drift of the 2000-foot level of the Imperial mine, is the hottest on the Comstock. The temperature, carefully noted, was found to be 150½ degrees.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

(FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.)

By Special Dispatch, Dated Washington, D. C., Jan. 5th, 1875.

FOR WEEK ENDING DEC. 22d, 1874.

HARROW.—David T. Gillis, Stockton, Cal.

GRAIN HEADER.—David T. Gillis, Stockton, Cal.

ANIMAL TRAP.—Garnos Richardson, San José, Cal.

SAFETY PIN.—Lucy Emma Andrewes, S. F., Cal.

WATER GAUGE FOR STEAM BOILERS.—Charles C. Redmond, San José, Cal.

CHUCK.—William F. Footbaker, S. F., Cal.

DISTILLING SPIRITS.—Robert C. Brooks, S. F., Cal.

LOCKING LATCH.—Henry Rogers, Eureka, Cal.

TRADEMARK.

FOR BOOTS.—S. W. Rosenstock & Co., S. F., Cal.

—The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest time possible.

WOODWARD'S GARDENS embraces an Aqueduct, Museum, Art Gallery, Conservatories, Tropical Houses, menagerie Seal Ponds, and Skating Rink.

[Business Notice.]

Mining and Scientific Press

A VALUABLE WEEKLY FOR

Miners, Mechanics and Manufacturers on the Pacific Coast.

Volume XXX of this first-class, standard journal commences with the year 1875. Its proprietors, having the successful experience of ten years publication of the Press, have no hesitation in saying that for the ensuing year the paper shall, in keeping with the times, reach a higher mark of merit than ever before. With our own printing press, folding machines,

Able Editors, Correspondents,

And skilled workmen in different departments of our now extensive and growing establishment, we mean to print a journal throughout the year, which all citizens, whether patron or not, may be proud of seeing published and supported on this side of the continent.

No kindred journal in America furnishes more real

Fresh, Novel, Interesting Information

In its volumes than the MINING AND SCIENTIFIC PRESS. We have the

Largest Mining Field in the World

To report from. It embraces the largest variety of mines and mining; methods of working; and innumerable wonderful discoveries than any other section of the globe. It is the birth place of many of the

Latest and Best Inventions in Gold

Silver and Labor Saving.

With brief, reliable, well chosen and prepared editorials; varied and condensed correspondence and selections; tables and statistics arranged for ready reference,

Superior Illustrations,

Of local and general interest to its readers, forms a weekly journal of individual character and unrivalled worth to its intelligent and industrial patrons at home and abroad. It is the

Leading Mining Journal of America,

And in its practical, interesting and substantial make up, it is unrivalled by any mining or mechanical journal in the world.

Home Manufacturers and Home Inventors

Will be constantly encouraged. Both help build up the brain and material wealth of the country. They are kindred to our individual enterprise. Our interests are mutual with a home atizens and producers. Where on the face of the globe do inventors and manufacturers either need or deserve more encouragement?

Its Value to the Community,

In disseminating important information; dissipating false notions; checking expensive follies; investigating important enterprises; by wise counsel and scientific direction, enriching the reward of honest labor, we are annually saving and adding

Millions of Dollars

To the products of our country. The Press has already

A Large Circulation,

And is deserving of more universal patronage from those whose interests it specially represents. This sparsely populated portion of the Union is a difficult one for publishers to present the claim of their journal in to all who should subscribe. In these times of seeming cheap (but largely, trashy and worthless) journalism, it is desirable and proper that those who know the real merits of a faithful journal should

Speak and Act in its Favor.

We shall not spare our efforts to make some and improved issues, maintaining constant the rights of all, and forwarding the material and intellectual rights of our patrons, and our sturdy, progressive community.

Necessarily, scientific and mining publications generally are costly and high priced, but considering the size, character and location of our publication, our rates are favorable for valuable a print.

We invite correspondence from all sections. Subscriptions, payable in advance, \$4 a year. Single copies, postpaid, 10 cents.

Address, **DEWEY & CO.,** PUBLISHERS, No. 224 Sansome St., S. F.

THE NEW OREGON MINES.—Speaking of the new quartz mines in Southern Oregon, the Times, of Jacksonville, says: "A late dispatch from Rock Point says J. L. Colvig and James Birdseye have just arrived at this place from the new quartz mines. They say the road is lined with men and pack-trains going to the land of gold and silver. The great Mammoth ledge is about 180 feet in width at a point where the Rogue river has worn its way through to a depth of 500 feet. About 200 claims are now taken up. It has been traced for twenty miles through a very rough country. Guides get from \$10 to \$20 a day to trace the lead. Colvig says he crushed a few pounds of the ore, and it averaged ten cents per pound in gold. A town has sprung up in a few weeks. It is to be known as Mammoth City. Hotels, feed stables, shops and other buildings are going up."

The first beds of coal were discovered in Washington Territory in 1852, and since that time coal has been discovered in all parts of the Territory west of the Cascade range.

ONE hundred and fifteen mining locations were recorded during 1874 by the Recorder of Tuolumne county.

FATAL INFATUATION.—Do not, as you value your life, entertain the idea that a cough is one of those casual affections which require but little attention. This species of infatuation is fatal to thousands. A cough is the first menace of consumption—remember that. Annihilate the danger by extinguishing the complaint. The means await you at every drug store. *Hall's Honey of Hyacinth and Tar* will, in every instance, effect a perfect cure of the threatening ailment without causing nausea, for it is pleasant to the palate as well as infallible.

Pike's Tooth-Ache Drops—Cure in one minute

AT THE PACIFIC MACHINERY DEPOT,

H. P. GREGORY,

Beale Street, near Market, San Francisco.

THE BIRMINGHAM SHOVEL.

These Shovels have No Rivets nor Straps.

The blade is made of one piece of BEST SOLID CAST STEEL, the blade and shank being one piece.

THEY WILL WEAR TWICE AS LONG

As the ordinary shovel. They are the STRONGEST, BEST and CHEAPEST SHOVEL EVER MADE. Examine the engravings carefully and you can see how they are made.

THEY NEED ONLY TO BE TRIED

To prove their value. Prices same as ordinary shovels. Ask for the BIRMINGHAM SHOVEL. Take no other.

TO COPPER SMELTERS, BLUE-STONE & SULPHURIC ACID MANUFACTURERS.

For sale or to lease the LEVIATHAN COPPER MINE, in Alpine county, California.

The ore, which is in the form of silicate, bluish and red oxide, and gray sulphide, with metallic copper finely disseminated, averages from two to five feet thick, and 15 to 50 per cent. copper. A few parcels taken out during exploratory operations, realized \$30,000 for Bluestone. In sight, 2,000 tons 20 per cent. ore; on dump, 300 tons 15 per cent. Supply inexhaustible. Title perfect. Minimum present capacity, 10 tons per day, which may be extended indefinitely. Cost of extraction \$2. There is also a stratum of sandstone 20 feet in thickness, impregnated with 25 per cent. pure sulphur. To a coin purchaser highly advantageous terms will be offered. For further particulars apply to Leurs Chambers, Silver Mountain, Alpine county, Cal.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING and TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

IMPROVED HOISTING ENGINES.

HOISTING ENGINES.

COOK, RYMER & CO.'S Celebrated Hoisting Engines have been too long in use on the Pacific Coast to require any special recommendation from us. We refer with confidence to any one of the hundreds now in use. We simply state that they still sustain their old reputation, the manufacturers not having followed the now too common practice of reducing the quality of material and workmanship for the sake of competing with cheaper engines. For details of sizes send for price list. We desire to call particular attention to our new

MINING HOISTING ENGINES.

(Manufactured by the same parties.)

Which have just been introduced on this Coast. The plans and specifications are the combined efforts of our most successful mining engineers, and the result is the most complete

DOUBLE-DRUM HOISTING ENGINE

Ever built. Their advantages will be seen at a glance by any one familiar with the necessities of a mine. One of these engines may be seen at work in the Belcher mine, and one in the Ophir, on the Comstock lode, to both of which we refer. We have all sizes of these engines constantly on hand. For sale only at

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

[PATENTED MAY 26TH, 1874.]
Price Reduced to 16 Cents Per Pound.
SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally.

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburg Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our Patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 50 days to fill orders from the manufactory East. Price 15 cents per pound shipped at San Francisco. Terms liberal.

Address all orders,

to

TEATS' PATENT FURNACE.

TEATS' PATENT FURNACE

For Roasting, Desulphurizing, Chloridizing and Oxidizing Ores, etc. For the reduction of Gold, Silver, Lead and other ores, saving a larger percentage, at less cost, than any other invention now in use. Chloridizing Silver ore more thoroughly, in less time, with less fuel, salt and labor; also roasting Lead ore preparatory to smelting, better and cheaper than any other invention. The Furnace is so constructed that one man, of ordinary ability, tends five or more furnaces; controls them with ease, adding heat or air; stopping or starting at will; charging and discharging with ease. Also, Patent "Conveying Cooler," for conveying and cooling roasted ores, heating the water for amalgamation and the boilers at the same time. Saving the large space in mill (covered with brick or iron), and the labor of two men per day, exposed to the poisonous chlorine gases. Also, Patent Air Blast "Dry Kiln" for drying ores direct from the mine or breaker, saving fuel and labor heretofore necessary in drying ores for dry pulverizing. For description refer to MINING AND SCIENTIFIC PRESS, No. 18, October 31, 1874. For particulars address

Cazin's Combination Ore-Sizer and Concentrator—One Plunger System.

[Covered by Letters Patent of July 2d, 1872, and recent applications.]

Containing a sizing apparatus, (revolving screen) delivering two or four sizes of ore to two or four rows of sieves, each row independent of the other, and each having 5 sieves, each row concentrating according to specific gravity the special size automatically fed into it, resulting in the simultaneous continual delivery of separated materials, working 2d and 3d-class ores into 1st-class ores of perfect cleanness. It thoroughly separates native gold or copper from quartz or any other lode matter—galena and silver sulphurets from pyrites, baryta and quartz; and pyrites from quartz.

Added to a battery of stamps these machines constitute a full system of ore concentration, sufficient in most cases for the requirements of western mines, with a capacity of 15 or 20 tons per 24 hours.

For particulars apply to,

F. CAZIN, M. & C. E.

Supt. Denver Concentration and Smelting Co.
At Denver, Colorado, Lock-Box 2225, or corner of Blake and 22d streets.

Hydraulic Mining in California.

No. 8.

Connections With old Workings.

The foregoing remarks about the opening of hydraulic mines refer chiefly to those mines or gravel deposits which, having never worked before, offer all the difficulties of new and undrained ground. Whenever other mines have been worked in the same deep gravel deposit, and a neighboring claim has reached its boundaries, thus setting free one side of the gravel bank, which shall be submitted to the hydraulic process, the tunnel can be connected with the free side by large drifts, constructed on a grade sufficient to receive sluice boxes. These drifts must be placed deep enough in the bed rock to permit the washing of the gravel into the sluice boxes from all sides.

It must be borne in mind that, under the conditions mentioned, the very gravel bank through which these drifts or cuts run will have to be washed away, and the closing up by cavings of the mouth of one or the other drift can hardly be avoided.

The best way to clear a mass of caved matter from the mouth of a drift is to wash a small channel close to the gravel bank, so that the caved matter itself forms a wall and barrier on the outside, confining thus the water and gravel work to a small stream. In this way an opening is soon made, and the bulk of the caved matter can be dispatched through the drift whose mouth was cleared.

The Working of Hydraulic Mines.

This is done by the power of water and powder. The power of the former depends on its quantity, and the pressure under which it can be applied. It is therefore most desirable to have the supplying ditch, or reservoir, not only at a high elevation above the mine, but also in its close proximity. The first condition insures a great hydrostatic pressure; the second a short line of feeding or conveying pipes.

To give an idea of what a powerful agent water can be made under pressure, it may be stated that a quantity of water, equal to a thousand inches, miners' measure, and yielding 1,579 cubic feet per minute, can be discharged under a pressure of from 275 to 300 feet, through a 6-inch nozzle, with a velocity of 140 feet per second, and in a quantity of 1,645 pounds, for the same length of time. Such a quantity of water uninterruptedly striking the bank, with one-tenth the velocity of a cannon ball, must necessarily do great execution, and suffices, in many instances, to produce the caving of the gravel bank, without resorting to bank blasting.

After a hydraulic mine has been opened for washing operations, a long line of sluice boxes, with under-currents, grizzlies, etc., laid down, and water under a high pressure connected through an iron pipe with one of the improved hydraulic nozzles, the real mining work can be commenced. The description of the different mechanical appliances will be given further on. At present the operation itself will be described.

A single hydraulic nozzle, connected by an iron pipe of any length, with a distributor—which latter is again connected with the feeding pipe, receiving the water from the bulkhead of a ditch or reservoir—has been placed at a safe distance from the gravel bank to be washed. A screw, attached to the distributor (for the purpose of opening or shutting a gate commanding the connection and flow of water between the distributor and the hydraulic nozzle,) is turned, and a stream of water issues from the hydraulic nozzle. This stream increases in size and strength as the gate opens more and more, and after a few minutes a body from five to seven inches in diameter, and representing from 500 to 1,000 inches, plays with magnificent force against the opposite bank of gravel. The water issuing from the nozzle is to the touch as hard as a bar of steel, and retains, when thrown from a good nozzle, its cylindrical and condensed shape, till it strikes the gravel bank. The effect of this lance-thrust of water against the bank is soon visible. At the first shock, a thousand rays of water fly in all directions; a little later, the lance has buried itself deep in the bosom

of the bank, and the water boils and hisses over the lips of the aperture, carrying with it gravel, sand, clay, and whatever matter may be at hand. The opening widens; flakes of gravel tumble in all directions; an arch, wide and deep, is made in the gravel bank. The "jams" of the arch to the right and left are demolished by turning the jet of water upon them, and the first "cave" in the hydraulic mine takes place.

Condensed from an article by Charles Waldeyer, of the last Annual Report of the U. S. Commissioner of Mining Statistics.

The Ladies' Friend.

We give herewith an illustration of a very useful device for dressmakers and those who have much cutting to do, it being really a lap

Improved Lap Board.

board upon legs which are so arranged that when not in use they can be folded up and fastened to the under side of the table so as not to be in the way. The cut shows the board opened out in readiness for working. The two pairs of legs, c, c, are hinged to the ends of the table, and have suitable bracing cross bars to keep them steady. At the back of the table the two cross bars, d, are hinged so that when opened their lower ends pass

Diagram taken from Engine at the New Mint.

through mortice slots in the legs, c, and are secured by a simple button, a, which fits into a notch cut in the brace. By this construction the whole table is rendered very steady and when it is desired to put the table away it is only necessary to fold the braces, d, down and the legs, c, c, across each other beneath the table where the whole can be held by means of a button shown upon the braces, d. In weight these tables do not exceed that of an ordinary lap board, and those who have tired themselves with holding one of the old kind, or who have seen the inconvenience of putting them down with all the work when they have to get up for anything, will recognize their value and the reason for calling them "The Ladies' Friend."

A patent has been obtained upon this invention through the MINING AND SCIENTIFIC PRESS Patent Agency by Mr. Benjamin Strawbridge, of Stockton, Cal., where he can be addressed for town, shop, or State rights or for single tables.

The shipments of treasure from British Columbia by Wells, Fargo & Co., during the year 1874, amounted to \$1,382,454.78, being more than any other year since 1868, and \$404,228.29 more than in 1873.

An Improved Harrow.

Frank Donohue, of Mayfield, Santa Clara county, has recently patented through the SCIENTIFIC PRESS Patent Agency an improved harrow, which we illustrate on this page. It is so constructed that by its natural hanging and draft, without extra weights, the outer edges will keep down to their work and preserve as nearly as possible a uniform level and penetration of the teeth. It is usual to employ a weight on each wing of a sectional harrow to keep the edges from buckling upward, but by the improvement of Mr. Donohue the harrow is so constructed that the edges will keep down without a weight.

Two hinged sections of a double harrow are made, each being rhomboidal in shape and consisting of as many parallel timbers as desired to hold the teeth. These timbers are united together by a transverse timber near each end. At one end of each section a partial parallel timber is secured, so that when two rhomboidal sections are placed together in the usual

Donohue's Improved Harrow.

way of uniting the two sections of a harrow, the two partial timbers of the two sections will stand in the same line, and will, in effect, be a divided timber in the middle of the harrow. The hinge straps or plates are secured upon the parallel timbers so that the hinges at the opposite ends of the harrow will come on opposite sides of the divided timbers. If a line should be drawn through the two hinges it would cut the harrow into two trapezoidal figures, thus causing the weight of the corners to be nearly at right angles to the breaking line or joints of the two hinges, so that their superior leverage, owing to their greater dis-

The Colusa Quicksilver Mines.

From a private letter to a gentleman in this city with regard to the quicksilver mines in and near Colusa county, we make the following extracts: The Abbot mine, which is just over the county line, according to the statement published by the Secretary, has produced since the first of October 125 flasks of mercury. They are said to have considerable quantities of ore in sight, and have flattering prospects. On the same side of the hill are several other "prospects." One of them called Excelsior, owned by Disturnell Brothers has turned out some very fine ore, having brought in for reduction considerable that has run from 11 to 15 per cent. The Excelsior is an extension of the Abbot on the south. Adjoining it on the south is another mine called the Jackson, which from all accounts is prospecting very well, having 30 or 40 tons of pay ore on the dump.

On the Colusa county side of the hill is the Elgin mine, which is about four miles from the present Wilbur Springs. The mine is under the management of J. O. Smith. They have one retort of about 800 pounds capacity per 24 hours. Mr. Smith started up the retort on the 20th of August, and has produced 52 tanks of quicksilver. They have some very fine ore in sight, and large quantities of furnace ore.

The Montezuma claim is owned by Hughes, Rood and others, who are having a tunnel run under their prospect on the surface. They have both gold and cinnabar ore. The Manzanita is one of the oldest claims in the district, and the most of it is owned by C. B. Hughes. It produces some very good ore.

The Buckeye mine, notwithstanding the difficulties they have had to overcome in law suits, lack of means, etc., has produced over 600 tanks of mercury since starting. The mine is looking very well. They cleared up last week, after seven days' run about twenty-two flasks of mercury, which would be from eighty to ninety per month. They expect to exceed this when the drain tunnel is completed. It is now in ore 500 feet, and the shaft will be reached in about 100 feet more. Two more winzes are being sunk from the main level, 150 feet apart, to the grade of the drain tunnel, and they will then work in from different directions. So that by March or April the Superintendent expects to have it right in the heart of the mine with a heavy body of ore overhead which they can break down as it suits their convenience.

The New Mint Engine.

Most conspicuous among the lavish equipments of the new Mint in this city, in the mechanical department, and claiming the attention of the numerous visitors, stands the massive high pressure beam engine, built by Booth & Company, with its polished engine bed, pillars, and entablature. We have already described this engine and now present a diagram taken from it with a Richards' indicator, one of the first taken. The diagram is on a scale of 30 pounds to the inch. The engine has a four-foot stroke, and had a comparatively light load at the time the diagram was taken, 9:30 A. M. The points to be deduced from the diagram are as follows:

Commencing with the stroke at the top of the cylinder we see the steam valve begins to shut at one-eighth and closes at one-third of the stroke (the points dotted) whence we have the expansion curve the remaining portion of the stroke and returning get a well proportioned lead of steam, shown by the rounded curve.

Starting from the bottom of the cylinder we have steam shut off at one-sixteenth, the steam expanding and falling in pressure, as shown by the expansion curve the remainder of the stroke. Returning we notice that the steam valve requires a little steam for cushioning, i. e. helping the piston over the dead point, which would give a rounded corner in the diagram similar to the top. The load is comparatively light and the pressure small, but it would be desirable for top and bottom stroke to give the same reading in points of cut-off, etc. The valves are each worked by a separate cam, and as this admits of independent and exact adjustment, doubtless are this the points we have remarked have been carried into practical operation by the very competent staff of mechanical engineers.

tance from the hinges, will cause them to keep closely down to the ground when the harrow is working.

The double-tree is attached to the harrow so that its middle will be in a line with the two hinges, and in order to accommodate it to the harrow, the inventor constructs it in two parts and hinges them together as shown. The draft will, therefore, be in a direct line with the hinges, and consequently the sections will have equal rise and fall, and as the diagonal corners are further away from the line of draft than any other portion of the harrow, they will keep close to the ground.

GROUND was broken, last week, at the yard of the Vallejo Ship-building Association, for the foundation of the first building that is to be erected. This is a two-story building, 75 long by 30 wide; the upper story being designed for use as a loft, on the floor of which ships are to be "laid down."

The coin dies of the United States mint at Carson for the year 1874 were defaced last Wednesday, with the usual ceremonies, all the officers of the mint being present.

CORRESPONDENCE.

- Among the Quicksilver Mines.

EDITORS PRESS:—Arrived here last evening by saddle from Capay valley, over a tolerably good mountain wagon road, the distance being from D. C. Ramsey's ranch, the highest up Capay valley, about 32 miles. But by trail up Cache Creek valley from same ranch, I could have reached Knoxville in about eight or nine miles, and that, too, over an excellent route for a good wagon road. From Ramsey's to Woodland, 46 miles of level road down Cache creek, thus making the entire distance to railroad at Woodland 45 miles. To Napa city it is 53 miles. It seems strange that Yolo county should fail to see that this little internal improvement is much needed in her own county, and where so small an outlay would be sure to return a quick profit. Private enterprise will soon take hold of it as a profitable investment, if the county does not move in the matter. After a weary day's travel it is truly a treat to dismount in so pleasant a camp, which, by the way, would be a fully incorporated city in Nevada State.

The whole aspect of the place here, however, speaks business, not town lot speculations, etc. One large hotel with ample accommodations for man and a good stable for horses. After an excellent night's rest, I sallied forth to take a peep into some of the beauties of a quicksilver camp. After a cursory view of the quiet, but yet busy town, I took a two mile walk up the fine graded road to the Manhattan Co.'s mines, under superintendency of Joseph Osborn, who being absent, Mr. Charles Howard kindly showed the various parts of the mine. The mining operations were being carried on very successfully under 'H. Greenman and J. H. Morse, Foremen. By aid of drills, powder, cars and long chutes the ores are very cheaply transported from their native beds to the reduction works, where I found Mr. Joseph Meyer, superintending the furnace operations. Time does not allow me to detail this furnace matter further than the simple statement that they run a Knox & Osborn furnace, of 24 tons capacity, and are working 16 to 20 tons daily, employing 65 to 70 men in all. Wages, to miners, \$45.00; helper, \$40.00; common laborers, \$35.00 per month and board, with cabin accommodations. Every thing seems to move along in a systematic, common sense order, and is done by first-class white labor. The deepest work in the mine is about 200 feet, but now finding plenty of good ore at a depth of not over 60 feet from the surface, where it is well ventilated and healthy working.

But I must pass on over the hills to the California company's works, on the Reid mines, 3 miles north of Knoxville. These mines, situated just across the line of Napa into Yolo county, are esteemed highly among valuable claims. Through the kind attention of the Superintendent, T. J. Hall, his Assistant, J. S. Lambert, and Stephen Maynard, Foreman of the mine, I had abundant opportunity to visit and examine the principal points of interest at the furnace and mine. The lower tunnel, through which as a thoroughfare, all the ore from the various tunnels and surface workings for the 300-foot above it will be discharged, is about 500 feet long, with a well ironed car track. Above this is another tunnel 600 feet long, with its cross sections and stopings. Above this is a still a third tunnel, between 400 and 500 feet long. And above, and "sky-ward" as they term it, are open surface workings, yielding good mineral, worked to the depth of 40 or 50 feet. They employ genuine first-class, intelligent labor in every part of their operations. They are using at present one of the best constructed Knox & Osborn furnaces, with ample condensing chambers with vapor draught extending nearly a quarter of a mile away, up the mountain side, thus freeing the whole premises of any danger from hurtful gases or mercury poison. Capacity of furnace, 24 tons daily. I noticed also, one peculiar feature, introduced by Mr. Hall with successful results for economy. The fine metal bearing dirt and gravel he concentrates by aid of water, so that he need pass but a small amount through the furnace and gets more satisfactory results.

The amount of metal yield varies according to quality of ore used; last week gave a yield of 40 tanks of 76½ pounds each, but some weeks run less.

They employ on all their works, including extensive wood and farm operations, 100 men. The company erect all necessary dwellings and own all improvements made on their lands.

They have plenty of water running through their valley into Cache creek and thence down Capay valley, past Woodland in Yolo county. Eight miles of easily graded road would connect them with the road at the head of Capay valley and thus enable them to reach their county seat, and also carry their metal over a beautiful down grade road to the railroad at Woodland. This California company alone

could soon build the road if allowed to spend the road tax collected by Yolo county from their hands on that road. As now situated, they feel that there is some injustice done them.

Napa county pursues a more liberal course with the Redington company, at Knoxville, in the disposition of road monies, and will be the gainer thereby. This Redington Quicksilver Mining company being a great representative mining operation has been fully written up and needs little to be said. Through the obliging clerk of the company, Mr. Hall, I obtained the following items—not having time to inspect the interior of the mine. Mr. C. E. Livermore superintends the entire operations.

They employ 250 men. They have three Knox & Osborn furnaces and one more is being erected. These are old style furnaces that work about 200 tons per week. The K & O. furnaces yielded about 600 to 1,000 flasks per month for the past few months. Plenty of good ore in the mine on the 400-foot level.

The company own the entire town and miles of surrounding lands, with a vast store of all the ordinary and extraordinary necessities; provisions, clothes, medicines, etc.; hotel and stable, shops, and even the church edifice, a very creditable emblem of civilization. Perhaps it is one vast monopoly! Who knows? If so, this fact failed to appear in any form of complaint from their tenants and operatives. I had a long talk with one who has been 8 years in their employ, and occupying a very responsible position. I heard no words of dissatisfaction. This same feature is common to all the three companies. Each having an entire ownership of extensive domain and supplying the principal wants of their operatives. They even employ a first-class physician at a trifling expense to each. Dr. Sweet, now employed by all three companies, seems very popular with all; but very little sickness in the camp. C. Knoxville, Dec. 25.

The Sumner Mine.

The Sumner mine, in Kernville, Kern county, is an old mine which has been worked for several years without profit, but which will shortly be heard from, and is likely to rank with the most famous mines on the coast. It might have lingered along, occasionally worked and oftener idle, had not the attention of Senator Jones been attracted to it about three years ago. It now belongs to the Senator and E. K. Banks. Since that time it has yielded \$8,000 to \$10,000 a month from so much ore as could be crushed by an old rattle-trap 15-stamp mill. Most of the time since then has been spent in perfecting the title, which was very much involved. The difficulties have all been removed, and United States patents obtained. The Sumner mine now includes the old Sumner and the Big Blue mines. The claim is 8,000 feet long, with a vein 60 to 80 feet wide, of which 15 to 40 feet is pay ore. The character of the rock is free milling. A new water power mill of 80 stamps is just being completed. Hoisting works of the most approved Comstock pattern, and larger than anything yet erected in California, are building, and will be finished in April, when the new mill will be set to work on \$35 rock, of which the mill will crush 160 tons a day. As the Kern river runs past the mine, and the productiveness of the mine with the new hoisting works cannot be estimated until it reaches the quantity necessary to feed 1,000 stamps. With such facilities a mine of this extent must contribute largely to the enrichment of its owners and the filling up of Kern county with inhabitants of every occupation. Senator Jones' investment in the mine alone is said to be \$500,000.

ALL ALIVE TO THE NORTHWARD.—L. H. Torp, keeper of the Gelger Grade toll-house, informs us that there was a straggling army of men on the move along his road to the northward last night, all excited about their mining claims in that direction. The time for doing the required \$100 worth of work expired at 12 m. last night, and the owners of claims felt that it was time for them to be up and doing. A great many parties of jumpers were out. Some whose claims are doubtless all right were out to guard against these and warn them away, while others who are probably not at all right went out in order that they might be found on their claims and at work when the hour of twelve should strike. The jumpers were very numerous, and it was feared that there would be bloodshed during the night. It is said that no less than four different parties went out north to jump a certain claim which all have been long watching. Those who first succeeded in posting their notice when the witching hour of midnight arrived would be the lucky ones. The parties leaving town went provided with provisions and otherwise fully equipped. Such was the demand for teams and riding animals that the stock of all of the livery stables was exhausted.—*Virginia Enterprise*.

CHEEKY.—Two well-known mining Superintendents of this city were yesterday discussing the bonanza, when one of them propounded the following question to his brother silver-hunter: "Supposing the Almighty to have given you full power and authority to make such a body of ore as you pleased, could you have made a better one?" "I don't know," said the other; "but I should have made it still bigger." "Well," said the first speaker, "you have more cheek than any man I ever saw—you have, by thunder!"—*Enterprise*.

The Sheep Ranch Mine.

A correspondent of the *Call* writing from Sheep Ranch mine says: Our camp being only eleven miles from the "big trees," tourists could make this call with scarcely any extra expense of time or money. Here is the well known Sheep Ranch mine, owned by Messrs. Ferguson, Wallace and Early, without paying the best, for the money invested, of all the mines in the State. Their mill is running continually. They have just finished new hoisting works at the old shaft near the east end of the claim, and are now reftumbaring it. Walter and I had a little game the other day. Faking a tub of water to the dump we tried to see which could find gold first. He rather beat me, but I believe we did not pick up a piece of rock that did not show gold. Sums of the ribbon rock was besprinkled with it. Now and then a little galena was seen, but this mine has but few sulphurates.

Adjoining, and on the same lead to the east, is the McNair claim. This has been prospected sufficiently to warrant the belief that it is a first-class mine. A shaft about one hundred feet in depth has been sunk, and considerable drifting and stoping done, the rock paying well. This mine has not been worked for several years, but a new shaft is about to be sunk near the west end, where, in the claim adjoining, excellent ore was taken out. There the water will not bother, as the contiguous mine has been worked up to the line. There is probably no better place for the investment of capital than right here, and I understand the claim is offered for sale, as the owner wishes to remove. Here on these mines were corralled for years a band of sheep, the shepherds daily stumbling over rich croppings, as unsuspecting of the wealth below as the woolly quadruped they tended.

A little to the south is a new claim owned by Messrs. Bean, Smith & Hicks. They have only crushed nineteen tons of rock, which paid \$61 to the ton. This mine was discovered by Mr. Bean, an old prospector, and one of the best on the mineral belt. A little further to the south is the Lodi. It has paid well, but has not been worked for the past two years. Messrs. Hull & Tichner, the present owners, are now preparing to resume work.

A little to the east is a new mine discovered by Joseph Mason; he is busily engaged in getting out good-looking rock. Near this mine is one owned by Messrs. Toon & Hull, which has not been prospected much on account of water. So all are at work.

COAL STATE.—Jeremiah Gibson has shown us a specimen of coal slate, taken from a discovery he has made but a short distance from this city. The substance is sufficiently carboniferous to burn with considerable coaxing, which the discoverer thinks is a splendid indication that genuine coal will be found on digging sufficiently far into the ground. It is to be hoped that these surmises will prove correct, and we shall be pleased to record the fact as soon as made clearly evident. So many indubitable evidences of the near presence of the genuine article have been found heretofore and subsequently dwindled to a fine point and finally to nothingness that faith in genuine indications short of the real article itself has become somewhat shaken. It is to be hoped Mr. Gibson will persevere in his prospecting labors in this locality and finally bring an undoubted specimen of coal. Such a discovery would be invaluable to this city. The gentleman named has already made several discoveries of material of a useful character.—*Deseret (Utah) News*.

WARD AND JULIA.—The *Gold Hill News* says that an agreement was entered into on the 23d ult. between the Julia Gold and Silver Mining company and the Ward Mining company, whose mine adjoins that of the former company, by which, for the space of eighteen months, the Ward Mining company have the privilege of working their mine through any of the levels of the Julia mine to the north line of the Ward claim, with the use of the tracks, shaft and hoisting apparatus of the Julia company.

THE NEW STANDARD.—A meter is three feet, three inches and three-eighths. Consequently, five centimeters are nearly two inches. The nickel half-dime is two centimeters in diameter, and weighs five grammes. Eight kilometers are nearly five miles. Sixty-six kilometers are about forty-one miles. Twenty-five millimeters make almost an inch. All this is to become familiar after the Centennial.

MINING DECISION.—The Secretary of the Interior has affirmed the decision of the General Land Office in the case of the Kempton mine, Utah. The question involved was the citizenship of the original locator and intermediate owners. The Secretary decides that applicants for patents must furnish proof of their own citizenship only.

A NUGGET weighing 68 ounces was last week taken out of the Bald Mountain, Sierra county. The company have again washed up the dirt in the small dump at the mouth of the tunnel, and the result was a dividend of \$1,000 to the share, \$20,000 in all.

JAMES MARION, a miner working in the Chalcedony mines, near Gibsonville, was last week found dead in a tunnel, having been suffocated with smoke from the engine room.

THE town of Panamint stands directly in the midst of the mines.

New Locations.

The *Virginia Chronicle* says: A large number of locations of mining ground have been made since the law of Congress took effect on the first of January. On this hills surrounding town notices are met with everywhere, some of which are in out of the way localities, which had been abandoned years ago, and where there is no more probability of finding a paying mine than out in the Twenty-six-mile desert. Perhaps, however, the object of these prospectors is to form companies, issue stock and dispose of it for whatever can be realized, as was common in Washos in early days. Some of the locations have been made in the most ridiculous manner, and without any regard to the points of the compass. Some run directly east and west and one at least extends 1500 feet directly across the Comstock ledge. What this mining sharp expects to accomplish is not easy to conjecture. Other property which has been taken up is really valuable. In some cases good claims had been abandoned years ago by the owners, who had followed other excitements and gone off to new countries, while in other instances companies had been working on properties to which they had no title, and took no pains to secure one, when the time arrived. A number of persons are still traversing the hills north and south of the ends of the Comstock, looking for eligible locations. The weather has been as propitious as if set apart especially to favor prospecting at the right time. Had the ground been covered with snow a foot or two in depth for the last week, nothing could have been done, but the mild temperature and balmy atmosphere seems to draw persons out into the hills for amusement as in the early days of spring.

GOOD FOR THE "C AND C".—There are those among our mining men who predict that the new C and C shaft now being sunk near the works of the Virginia City Gas company, will strike ore before attaining a depth of 600 feet. This would be a big thing and a fine send off for the C. and C. We all know that General Thomas H. Williams found fine prospects three or four hundred yards further east in boring down from 600 to 800 feet with a diamond drill. The progress of the C and C shaft will be watched with the keenest interest by all our mining men, as all have looked upon the surface configuration of the ground thereabout with a wistful eye. In the whole basin extending across the eastern front of all of the bonanza claims nothing that could be called a shaft has ever been sunk—nothing but the old-fashioned circular prospect holes.—*Enterprise*.

FOUNDRYMEN EXEMPT FROM LICENSE.—An agreed case was recently made in this city to test the power of the City License Collector to demand license tax from foundrymen. Mr. Palmer of the Miners' foundry was arrested for refusing to pay license and the case went to trial. The defense set up in this case was that the defendant and his partners only manufactured articles in their line of business to order, and did not keep any merchandise on hand for sale. The court held that this was not a vendor within the meaning of the law, and therefore dismissed the complaint.

PANAMINT is supplied by water from spring located in the cañon above town, brought down in pipes and retailed at present at five cents per gallon. The supply is and will be ample for quite a city, and may be increased indefinitely by wells of about 100 ft in depth, two of which are now in use. About a sluice head of the finest water bursts out two miles down the cañon and continues to the sands three miles below, and along the only road by which team can reach the town.

THERE are on exhibition at the office of Samuel Poorman, Sacramento, two bars of silver weighing 216 pounds, and valued at about \$4,000, smelted at the Sacramento smelting works, from ore which had been looked upon as very difficult to reduce, but the new superintendent finds no trouble in reducing it by simple process of his own.

THE *Tribune*, in its annual review of the mines, says that Utah produced in 1874 near \$8,000,000 in silver bullion. This is nearly double the product of last year, and places Utah next to California in the production of the precious metals.

THERE are some of the richest gravel mines in the State near Central hill, Calaveras county. A clean-up of the Haskins claim, after washing the gravel obtained by two week drifting, yielded 180 ounces of the precious metal.

ORE SHIPPER.—Captain Richards shipped yesterday four car loads of copper ore for Battle Mountain to San Francisco. The ore from the English company's mine at Copper canyon, and will be shipped from San Francisco to Liverpool.—*Silver State*.

THE old Green mine, on Gold canyon, short distance below the Justice, after a rest a couple of years, is now being reopened with view to its thorough practical development under the superintendence of W. W. Turner who is also superintendent of the Pictou.

LAST week, says the Lake County Bee, W. Williams discovered a ledge of silver bearing rock in the vicinity of the Highland Spring. On last Tuesday a ledge, supposed to be of the same character, was discovered in Scott's valley.

MECHANICAL

PROGRESS.

Improvements in Glass Manufacture.

Considerable attention appears to be given at the present time in relation to improvements in the manufacture of glass, with a view to its more general utilization. The latest announcement we have noticed in this direction is the following: A French chemist professes to have discovered the secret of a chemical composition which has the property of giving to glass extraordinary hardness. Immersed in a bath of the new invention the ordinary material acquires such a degree of cohesion that it opposes to shock of hard bodies or action of fire a resistance ten or fifteen times greater than before. The novelty of the discovery is evident, as, if employed windows will not be broken by hail, and up glasses will not be cracked by the flames; and many even fall from a height of several yards without danger. The material being no longer fragile may be employed for many uses for which it is not at present fitted.

A French journal of a late date alludes to the above invention as follows: "The invention is termed 'steeped glass'; that is, a glass which has acquired its peculiarity by liquid absorption—by being 'steeped' in some liquid. A number of experiments were made with the 'steeped glass' at Bourg, where a company had been organized to introduce the article into commerce. A sample of only three millimeters in thickness resisted the weight of 100 grammes falling from the height of five meters. Thrown on the ground with force it rebounded without breaking, and emitted a sound like a leaf of metal; and, in fine, it was found to be incombustible to any definite heat. The company will first introduce it in kitchen articles. This seems to be the re-discovery of one of the lost arts of the ancients, which was well known to the artificers of the Ptolemies, and even as late as the time of Archimedes. It promises to make a revolution in the material of nearly every article of domestic utility.

[We have taken measures to learn more definitely with regard to the truth or falsity of this asserted invention, and shall communicate to our readers whatever information we may obtain as soon as received.—Ens. Press.]

Single Rail Steam Towing on the Belgian Canal.

We learn from the *Moniteur Industriel Belge* that a system of steam towing is about to be established on the Bourgogne canal, over a distance of about 150 miles. The tow path will be laid with a single rail weighing some 16 pounds to the yard, and fixed on traverses placed 3-2 feet apart. The locomotive has four wheels, two of which are placed directly along the axis of the vehicle, one in advance of the other, and two, one at either side. The former are directing, the latter driving, wheels. The directing wheels are grooved, and fit the rail; the others have rubber ties which give purchase on the macadamized road, and which rest thereon only to the extent of 0-07 pounds per square inch. By means of simple mechanism, the weight of the machine may be thrown either upon the driving or directing wheels at will. In the first case the maximum and in the last the minimum of adhesion is obtained, to suit the conditions of a loaded or an empty rail. A single road is to be used, with relay engines provided at suitable distances. Each locomotive tows one boat; and when a meeting takes place of two traveling in opposite directions, the engines change boats and retrace their paths.

This single rail system has already been satisfactorily tested for short distances on the Belgian canals, and the projector, M. Larmanet, has obtained a government concession for its extended construction for 40 years. The locomotives are to weigh four tons each, and will travel at the rate of 3-1 miles per hour, with full boats carrying a cargo of 150 tons each.

INDIA-RUBBER TIRES.—Messrs. Bird & Co., London, have lately brought into notice a new and improved wheel, with India-rubber tire, which is claimed to be capable of wearing long as, or longer than an iron tire, and to give the great advantage of perfect noiselessness and absence of injurious jar. The draft of the carriage is said to be reduced by the use of this tire nearly one-third. It appears to be simply a tire of solid rubber, fastened on the interior of an ordinary wheel by bolts, such as are used with iron tires, and it may be thinner than the usual kind, merely serving the purpose of a band to hold the wood work firmly together.

A HANGING railway car, suggested by Mr. Beyer's steam system, has been tested with success on the northern railway of France. Mounted in this car, which hangs on elastic springs, the traveler experiences the sensation of a hammock, free from vibrations and bumping. The movement is described as very gentle.

IMPROVED STUCCO.—M. Landrin, recommends a mixing of the crude plaster in water containing 8 or 10 per cent. of sulphuric acid. After allowing the compound to rest for fifteen minutes, he calcines the plaster. This gives a stucco of excellent quality in which all ganic matters are burnt out leaving the material of exceptional whiteness.

Relative Cost of Water and Steam Powers.

The cost of the water power equipment at Lowell, for canals and dams, \$100; for wheels, etc., another \$100, per horse power. But this, as a first experiment, was more costly than a similar equipment need be. At Saco the expense incurred was \$175 per horse power; but at a later period, for turbines with high heads, the expense would be less. A construction and equipment, solidly carried out, with the latest improvement in wheels, would not cost over \$200 for horse power, and would, under favorable circumstances, cost less. An estimate at Penobscot was for \$112.50 per horse power. If the construction be with wooden dams, and the equipment with lower grade wheels, then the cost would be about \$50 per horse power; and although the construction would be less permanent than the more solid, it would outlast any steam apparatus. On the other hand, Fall River estimates of steam equipment, exclusive of foundations and engine houses, run from \$100 to \$115 per horse power. A Boston authority gives \$115 per horse power for nominal 300 horse power and upwards, inclusive of foundations and masonry. Similarly a Portland authority places it at \$100 per horse power. The actual cost of steam equipment in the water works of various cities of the United States varies from \$150 to \$300 per horse power.

As to the cost of work done, it appears that in Philadelphia in 1867 the cost of raising water by water power was only 2½ cents per 1,000,000 gallons feet; whereas the cost by steam power was in four cities 8-3-10, 11-1-10, and 19-1-10 cents, with coal at \$5.50 per ton.

A New Wonder in Steam.

A correspondent of the *American Manufacturer* writes from the vicinity of Pittsburg, Pa., as follows:

A conundrum for steam engineers to solve: Two gentlemen who engaged in engine building on the North Side, one of whom is largely interested in Butler county and Alleghany oil regions, made a special trip this week to the Steel (originally the McClutock) farm, to investigate a new system of using and utilizing steam power. The owner first had a 40-horse-power locomotive boiler, and had attached, separately, with the boiler two engines with 12x8 inch cylinders, to pump wells, making each 56 revolutions per minute. He afterwards attached a third engine to work from the escape steam from one of the first engines, which made 65 revolutions. He then detached one of the first engines from the boiler and worked it by the escape steam from the second, being successful in running three cylinders of same size. He then branched off the escape pipe from the third engine, and is now running two of the same power by the escape steam, after doing duty in three next the boiler, all being same size, and two last escaping in the open air, the boiler only consuming one-half the fuel as when all connected separately. My informant being fully satisfied of the facts as stated, left orders with his manager to experiment on the farm of his company, having quite a number of wells now pumping by separate engines. Now who will be able to account for this new increased power from one-half the fuel consumed, if by adding engines indefinitely and gaining power by each additional attachment, we have room yet to learn something about steam power.

A NEW PAPER BOARD.—A new method of manufacturing paper board, to make that article more generally useful and durable, is described as follows: When a sheet of paper is immersed in an ammoniacal solution of copper, and then dried, it is said to be quite impregnable to water, and does not lose this quality even though the water be boiling. Two sheets of paper thus prepared, and passed through a cylinder, adhere to each other so completely as to be quite inseparable. If a large number of sheets so prepared be cylindered together, boards of great thickness are obtained, the resistance and cohesion of which may be increased by interposing fibrous matters or clothes. The substance so prepared is quite as hard as the closest grained wood of the same thickness. The ammoniacal solution of copper is prepared by treating plates of copper with ammonia of the density of 0,880 in contact with the atmosphere.

IMMENSE PHOTOGRAPHS.—Photographs have been made of the new Opera House, Paris, four feet three inches in length, and three feet four inches in height. They were obtained in one single piece, by well known processes, and with the aid of a large and specially constructed camera. All the lines of the pictures are of remarkable excellence, the moldings, the busts, the medallions, and even the minutest details being reproduced with rare perfection. The attempt is being made to secure pictures even larger than this.

PAPER MANUFACTURE.—Upwards of one hundred firms are engaged in the manufacture and sale of paper in Philadelphia, the first established in the country being the Rittenhouse Mills, where the old Continental paper money was made. At the present time all our bank note and fractional currency paper is made by the old and wealthy firm of J. M. Wilcox & Co., of that city.

SCIENTIFIC

PROGRESS.

A NEW BLEACHING MATERIAL.—The essence of terebinthina has recently been found to possess extraordinary bleaching properties. Nearly every kind of organic matter subjected to its action becomes rapidly bleached. The discovery was accidentally made in the Jardin des Plantes, while soaking the skeletons of birds in the essence of terebinthina, for the purpose of cleansing them of the fleshy matter adhering to the bones.

[The "essence" above referred to we presume is obtained from the terebinth tree—*P. Terebinthus*—of the genus *Pistachio*, form which resinous substance known as *Chian turpentine* is obtained. This tree flourishes in the island of Chio. One of the varieties of the tree produces the *Pistachio* nut, the kernels of which are of a green color, and of a very agreeable flavor. The discovery may prove of some considerable importance.—Ens. Press.]

PHENOMENON IN IRON DRAWING.—In drawing certain numbers of iron wire, it often becomes necessary, in order to continue the use of the drawing bench, to anneal the iron. This is done in a hermetically closed receptacle, so as to avoid, as much as possible, the oxidation of the metal. In spite of this precaution, however, the latter becomes covered with an ochraceous film, which it is necessary to remove by an acidulated bath. It frequently happens, however, that, subsequent to this process, the metal becomes so brittle as to render its further drawing impossible. M. Serrez, engineer of the Societe des Forges de La Frenche Compte, has examined into this phenomenon, and finds that the iron becomes charged with a condensed gas. On breaking the wire under water in a test tube, inflammable bubbles were generated, which detonated in the air. The exact nature of the gas has not yet been decided, nor that of its direct action upon the metal; but it is believed to be either hydrogen or carbonic oxide.

SCIENTIFIC DISCOVERIES IN CYPRUS.—It is reported that Dr. Dethier, director of the museum at Constantinople, has, in conjunction with the American Consul General, Signor Cesnola, secured an interesting collection of antiquarian objects in the island of Cyprus. The mass of treasures accumulated by these indefatigable explorers was so great that more than a fortnight had been absorbed in packing the forty-four crates and thirty chests required for their reception. The discoveries of M. M. Dethier, and Cesnola include several cylindrical grave-stones bearing Greek inscriptions, which may probably be referred to the early Christian ages and the closing period of paganism; but here, as in numerous other remains of the same kind, there is no trace of a cross or any analogous religious symbol.

IMPROVED CHROMO-LITHOGRAPHIC PROCESS.—Messrs. Johnson, of Hatton Gardens, London, have invented a new and very economical process for producing chromo-lithographs. In place of using a special stone for each color, necessitating as many separate impressions as there are colors, the entire subject is drawn upon a single stone and a proof is taken on a thin sheet of copper. This sheet is then cut out carefully according to the desired contour of the colors, and upon each of the portions is fixed a solid block of color previously prepared. The whole is combined into one form, and is printed on an ordinary press—all the colors at once.

ELECTRO-MAGNETS FOR BLASTING.—An officer in the French army has communicated to the Paris Academy of Sciences the results of experiments during the siege of that city, which, he believes, may prove important for firing military and other mines. It is found that, when two bars of soft iron, armed with thin coils, are placed side by side, and one is magnetized, the other becomes also magnetized by induction, and the charge of the second is nearly twice as strong as that of the other. Hence the idea originated of employing auxiliary bars to increase the power of the coil used for such purposes.

ELECTRICITY AND MUSCULAR ACTION.—Scientists and the afflicted will await with interest the result of a trial of electricity in support of a pedestrian in a prolonged feat. In connection with a challenge to a rival he announces his purpose to rely largely for physical support upon the electrical bath as administered in all the large cities. The test will doubtless attract great attention and perhaps develop facts but little understood by the general public.

SUNSPOT AND OZONE.—If it would appear from the records of Mr. T. Moffat for nineteen years, 1851-1869, that the maximum of sunspot gave a maximum of ozone, and that the minimum of sunspot gives the minimum of ozone. The years 1854 and 1863 appear to be exceptional. In 1854, however, ozone observation at Hawarden were suspended for three months; which may account for the irregularity in that year.

PROFESSOR MARSH and party returned to New Haven from the West on Saturday, Dec. 12. The scientific results of the expedition are important, and will soon be published.

The Great Telescope.

The magnificent donation of Mr. Lick, of this city, for the construction of a telescope which shall embody all that science and mechanics, at the present day, can do to reveal to us more of the wonders of the starry universe, has excited much attention all over the world. Already a competent scientist has been commissioned to visit the leading observatories of Europe and learn all that can be of advantage to the commission designated by Mr. Lick for carrying out his praiseworthy purpose.

Previous to Mr. Lick's purpose in this direction heing made known, measures had been taken in France to construct a telescope of mammoth dimensions. This was first projected by M. Foucault, in 1865, but was laid aside in consequence of the death of its projector. It has since, however, been resumed under the direction of a well known astronomer, Mr. Wolf, and the construction of the instrument is being pushed forward as rapidly as possible. The tube of this gigantic instrument is nearly 50 feet long, and 6 feet 8 inches in diameter, while that of Herschell's is only five feet. The reflector is to be produced at the Saint Gohin glassworks, and the production of the mould alone, which is already completed, occupied six months. The mirror will be produced spherical, and will afterwards be worked up nearly to a parabolic form; finally it is to be covered with silver or gold. It is said that the staircase and stages to be used with this giant telescope will present fine specimens of mechanical ingenuity. The power of this instrument will greatly exceed any telescope hitherto constructed.

The experience gained in the construction of this will doubtless afford many useful hints in the construction of the San Francisco instrument, which will probably not be commenced until the former is completed. The Lick telescope will greatly exceed the power of the French instrument, and will no doubt furnish some most important revelations in astronomical science.

NEW DISCOVERIES IN THE MAMMOTH CAVE.—Professor F. W. Putnam, of the Peabody Academy of Sciences, Salem, Massachusetts, has recently explored the Mammoth Cave in Kentucky in the aid of science, and has visited several caverns never before entered. His investigation have resulted in finding colored fish without eyes, thus exploding the theory hitherto held that all eyeless fish are colorless. White fish with eyes, and crayfish both with and without those organs, were obtained, presenting many new features of great interest to naturalists. Skeletons of human beings, monnds, and a large variety of valuable archeological relics were found in the new chambers.

A new quality has lately been discovered to reside in autumn crocus, meadow saffron, or *Colchicum autumnale*, formerly used as a remedy for the gout and rheumatism—that of emitting a poisonous exhalation when its blossoms are opening. The touch of the flowers then imparts to the skin a yellowish green hue, described by M. Isidore Pierre, of the French Academy of Sciences, as being like that which "characterizes the human body in the early stages of decomposition." The effect passes off in a few seconds, but continued handling of the flowers in this stage induces numbness in the hand for some hours.

PROFESSOR YOUNG, of Dartmouth college who was one of the observers of the transit of Venus, will return home by way of Egypt and India. He and Professor Watson, of Michigan University, intend to make meteorological and astronomical observations in those countries. Professor Davidson, of this city, it will also be recollected will return by way of India, for the purpose of making scientific observations in that interesting portion of the East.

SCIENCE PROVING ITS FRUITS.—Professor Tyndall's experiments on sound are already bearing fruit. The French government has appointed a commission to conduct experiments upon a steam organ—the Calliope—heard 15 leagues in fine weather at sea. These new experiments are to be made during the period of the equinoctial gales.

IRREGULARITY IN THE EARTH'S ROTATION.—Professor Newcomb, of the Naval Observatory, Washington, asserts that the time of the earth's rotation on its axis is not strictly uniform. For twenty years prior to 1860 the rotation was slightly slower than the average. Since 1860 it has been accelerated.

SPONTANEOUS COMBUSTION.—In a paper on the spontaneous combustion of hay, H. Ranke says that in consequence of a prolonged fermentation, hay can be transformed into a true coal, which, when exposed to the air at somewhat elevated temperatures, acts as a pyrophorus.

An encouraging feature of the times is the increase in the number of scientific lectures, and the advance made in scientific literature.

PROFESSOR W. D. Whitney has been elected an honorary member of the London Philological Society.

Mining Stocks.

While there has been considerable excitement in the stock market during the past week prices have declined very materially. The cloudy and rainy weather seems to have had a depressing effect, though the contrary should be the case. The "little piece of porphyry" struck in Ophir has had the effect of tumbling that stock down and bringing others with it. The decline is not considered permanent, and most people think it is not yet time for the big break. The letter from California dated the 10th says:

On the 1400-foot level, 200 feet north of the southern boundary, cross-cut No. 1 is now in 203 feet, and has penetrated the ore vein a distance of 25 feet. The ore vein as crossed varies very much in value, assaying from \$52.80 to \$300 per ton. The face of the drift to-day does not look so favorable as it did yesterday. Judging from the cross-cuts on the level below, the vein on this level must be of great width. On the 1500-foot level east cross-cut No. 3 has been extended the past week 10 feet, and is now in 98 feet. The ore is identical in appearance and value with that found in cross-cut No. 1 on the southern boundary. Cross-cut No. 2, 100 feet from the southern boundary, is now in 78 feet, and has not as yet reached the ore body. The rock passed through is very hard. Cross-cut No. 1 on the southern boundary is now in 230 feet. The ore passed through the past week and now in the face of the drift is of a very high grade.

A dispatch three days later than the letter states that the rich ore improves in the face and all signs of the wall have disappeared. The ore is now 314 feet broad. The new shaft is 1040 feet east of the old one. One-third of this distance is already covered by the ascertained breadth of the ore, and the same trend of the vein may carry the No. 1 cross-cut quite to the new shaft, which will then not be far enough east.

The Lady Bryan trustees have caught the "increase of capital stock" fever. They propose with the consent of the stockholders, to increase from \$50,000 to \$300,000—six for one.

The Iowa mining company also propose to increase the capital stock from \$3,000,000 to \$9,000,000 in 90,000 shares.

The dividends declared this month are as follows: Belcher, \$3 per share, or \$312,000; Crown Point, \$2 per share, \$200,000; Consolidated Virginia, \$3 per share, \$324,000; Enreka Consolidated, 50 cents per share, \$25,000; Rye Patch Consolidated, 25 cents per share, \$7,500. This makes a total of \$868,500.

San Diego county yielded \$193,000 in gold bullion in 1874. There are now 60 stamps at work in Julian and Banner districts, and the yield for 1875 will be much larger.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's Office, San Francisco.

ORIGINAL FLOWERY M. CO., JAN. 7.—Location: Flowery district, State of Nevada. Capital stock, \$5,000,000, in 50,000 shares. Directors: R. H. Graves, O. H. Bogart, Thos. R. Hayes, R. C. Dyer and D. L. McLaughlin.

ALLEN CONSOLIDATED M. CO., JAN. 7.—Location: Storey county, Nevada. Capital stock, \$2,500,000, in 50,000 shares. Directors: Jas. A. Pritchard, F. Vassault, Geo. M. Pinney, Joseph Clark and T. J. Owens.

JACOB LITTLE CONSOLIDATED M. CO., JAN. 7.—Location: Storey county, Nevada. Capital stock, \$100,000,000. Directors: Jacob A. Pritchard, Louis A. Booth, Martin White, Aaron M. Burns and Wm. M. Pierson.

SILVER CENTRAL CONSOLIDATED M. CO., JAN. 7.—Location: Devil's Gate and Chinatown mining districts, Lyon county, Nevada. Capital stock, \$10,000,000. Directors: George Atkinson, A. B. Forbes, Jas. Duff, Oliver Eldridge and Adolphus Walz.

ALHAMBRA MINING M. CO., JAN. 9.—Location: Storey county. Capital stock, \$5,000,000. Directors: Fred Clay, C. D. Morrison, John Sroufe, S. Schreiber and R. Von Pfister.

COLUMBIA S. M. CO., JAN. 10.—Location: Virginia district, Nevada. Capital stock, \$10,000,000, in shares of \$100 each. Directors: Thos. B. Lewis, John Skane, L. Goodwin, T. H. Graves and P. J. Kennedy.

HUMBERT MILL AND MINING CO., JAN. 10.—Location: State of Nevada. Capital stock, \$5,000,000. Directors: George G. Barry, Hill Beachy, J. Guisaca, R. H. Brown and D. Hardy.

CALIFORNIA LINEN CO., JAN. 11.—Object, to purchase, sell, lease and rent real estate; erect buildings thereon; to purchase coal and sell patent rights; to manufacture goods from ramie, fax, cotton, wool and silk; to erect proper machinery, etc. Capital stock, \$1,000,000. Directors: Henry F. Williams, Wm. W. Hanscom, Charles E. Barnes, W. K. Doherty, George Bowser and D. McLaren.

BONANZA M. CO., JAN. 12.—Location: Utah Territory. Capital stock, \$10,000,000. Directors: P. B. Horton, G. H. Simpson, J. H. Johnston, D. C. McGlynn and Jacob C. Johnston.

The following named company has filed a certificate of incorporation in this office of this County

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR COUNTY.

DOWN'S GRAVEL CLAIM.—Amador Ledger, Jan. 9: On Saturday last we visited the claim of R. C. Downs & Co., located on the gravel range lying between Jackson and Sutter creek. It will require considerable labor and money to place the claim in thorough working order, but the company have before them an immense gravel deposit which will require years to exhaust. With the fall (over 2000 feet) aided by the Little Giant, a vast amount of gravel can be run off daily through the sluices. As work advances into the hill, the depth of gravel rapidly increases, and before the crest is reached a face of gravel of over 200 feet will be presented, all of which, from the top to the bed-rock, contains gold.

THE VOLUNTEER QUARTZ MINE.—We are informed that a rich strike was made in the Volunteer mine, near this place, on Tuesday last. The yield of the rock taken out on that day is estimated by good judges to be not less than \$1,000. The rock taken from this mine has paid well from the surface, and increases in quality and richness as the shaft is sunk.

LOOKING WELL.—We learn from Plymouth that the mining prospects of the neighborhood look very flattering.

The Phoenix mine presents a prosperous appearance of ore developed of a high grade.

The Alpine never looked more promising than at present. The main shaft is now down 700 feet with a ledge of pay rock ten feet in thickness, more well defined walls. The quality of the rock improves as greater depths are reached.

CALAVERAS COUNTY.

SCARCITY OF WATER.—Calaveras Chronicle, Jan. 9: The long continued drouth, together with the cold weather in the mountains, is beginning to tell on the supply of water in the ditch. There is scarcely enough to meet the demand at present, and indications of an increase in the near future are not favorable. There is no use in talking; we must have rain.

SINKING COMPLETED.—The sinking of the shaft in the Gwin mine, a hundred ft from the 900-ft level, is completed. The work of running the 1000-ft level, for the purpose of striking the north bonanza, will be immediately commenced. Meanwhile the batteries are steadily employed crushing ore from the levels above, and everything connected with the mine is in an eminently satisfactory condition.

UP COUNTY GLEANINGS.—Citizen, Jan. 9: At Mosquito, the claim owned by Skinner and Luftranchi is being tested by a shaft sinking from the tunnel. The tunnel is run on the vein for a distance of 500 ft and rock above stopped out. The average of ore crushed from the mine has been about \$48 per ton, while we are informed that refuse rock has paid from \$8 to \$10 per ton.

MISCELLANEOUS ore is being hauled from the Josephine to Harris' custom mill for crushing.

Work was recommenced on the Champion last week, the rock looking as well as that recently crushed.

GOULSON & HURBERT had a crushing from the lode lately discovered by them; and were well satisfied with the result. They are still taking out rock.

The new mill on the Enterprise was started last Wednesday.

HENRY & SON having purchased the Thoss mill have repaired it and will commence running in a few days.

The Zacatera has paid off a portion of its debt, and will shortly pay the balance.

EL DORADO COUNTY.

AN IMMENSE STRIKE.—Mountain Democrat, Jan. 9: Information reaches us from Georgetown that in the Woodside mine a five foot ledge has been developed, and our informant, possibly with more force than elegance, assures us that "the quartz is perfectly lousy with gold."

GEORGETOWN ITEMS.—The mining interests of this section of the county are looking up. The Cedarberg company (which I believe is the only one in our county), are drilling holes at a rate that would astonish any one not conversant with the working of the same, and is a decided success.

The International mine, Colonel Belty, superintendent, has developed a large ledge of ore filled with sulphurets, the rock assaying as high as \$1,300 per ton.

The Taylor mine is at present crushing ore at the rate of fifteen tons per day, and under the management of Mr. Walter Schmidt will prove a success.

The Garden Valley Co. have commenced operations of a permanent nature. This mine is an extension of the Taylor mine, and from present indications will prove a success.

LAKE COUNTY.

MINING ITEMS.—Lake County Bee: Ledges of silver bearing rock have been discovered in the vicinity of Highland Springs and in Scott's valley.

A well-defined ledge of gold-bearing quartz

has been discovered on the ridge that divides the waters of Russian river and Clear lake.

MENDOCINO COUNTY.

MINING DISTRICT.—Mendocino Democrat, Jan. 9: The miners hereabout met last Thursday and organized the Ukiah mining district, electing S. Wurtenburg, Recorder. The U. S. general mining laws were adopted; twenty days to record, a claim 1500 feet on the ledge, 300 each side. The district starts from Sanel district on the south, and runs up to neighborhood of Little lake.

The miners of our Ukiah silver mine are preparing to send a ton of their ore to the city for reduction, as a test of the working capacity of their mine. Assays are made from small specimens of ore, and are, consequently, often deceptive; but it is believed that a ton of the ore will give a reliable knowledge of the richness of the mine.

NAPA COUNTY.

NEW DISCOVERY.—St. Helena Star, Jan. 7: Dr. Michel and J. J. Dickinson have struck a three-foot copper ledge on their chrome iron claim, in Mowee canyon. It is very rich ore, and we should judge will go over fifty per cent. Anyone who may wish to see a specimen, can do so by calling at Dickinson's store.

LIVELY QUICKSILVER TROUBLES.—Napa Reporter Jan. 9: In the Fifteenth District Court on Thursday, a week ago, the Mammoth Consolidated quicksilver company commenced suit against the London quicksilver mining company, to recover 15,000 feet of ground of the Mammoth ledge situated in Lake county. Suit was also brought by Isaac Frank and others, against W. W. Cook and Aaron Cook, to recover 13,200, or 3,000 feet of the Oriental quicksilver mining ground in Lake county. The Mammoth Consolidated quicksilver mining company also brought suit against the Lake County quicksilver mining company, to recover possession of 4,000 feet in length by 1,000 feet in width of the Mammoth location. The Mt. St. Helena quicksilver company also commenced suit against the American quicksilver company to recover 2,700 feet of the Dead Broke, or Mt. St. Helena company's ground in Lake county.

NEVADA COUNTY.

OLD BLOCK MINE.—Grass Valley Union, Jan. 4: John Trenberth and others are working on the "Old Block" mine, which is located somewhere in the neighborhood of Grass Valley slide. Trenberth says they are putting down a shaft, and they are preparing to put in a "ninety." A "ninety" is a big steam engine, we believe.

OMAHA MINE.—Work on the Omaha is still being prosecuted with vigor, and the mine continues to show well in good milling ore. The ledge is now nearly four feet in thickness and free gold can be seen in satisfactory quantities all through the quartz.

NEW TUNNEL.—Transcript, Jan. 1: The South Yuba canal company, are running a tunnel about 1,200 feet long under the hill beyond the Manzanita mine, for the purpose of conveying the water of the Snow Mountain ditch through it to the town and adjacent mines. The work was considered necessary, from the fact that the Manzanita company have washed away the hill nearly up to where the present ditch runs, and there is a liability of there being a cave which will carry away the ditch at any time, and shut off not only the mine, but the town from water. The tunnel is eight feet wide and six feet high. Men are at work on both ends, and they have about 650 feet completed. The work was commenced in October, and will be completed in about two months more. It is under the supervision of John W. Hart, who is doing a first-class job.

The North Bloomfield mining company are at work piping and using their long tunnel for a flume. We understand it works to a charm and it is thought it has capacity enough to run off all the dirt they have water to wash.

The Union gravel mining company have completed their tunnel at Kennebec hill, and are taking out gold in large quantities.

ROCK STRIKE.—We understand very rich rock has been struck in the Home mine, situated on Deer creek about two miles below town, just in front of the Wyoming mine. The ledge is owned by the Hon. Thomas Findley. Machinery and hoisting works were erected on it several years ago, and work done on it, but for some cause it was shut down. Recently work was again commenced and we learn very rich rock has been struck. We are pleased to hear of any rich strikes and are none the less glad because Thomas Findley is the owner.

PLUMAS COUNTY.

DUTCH HILL.—Plumas National, Jan. 2: The water was turned into the North Fork company's big pipe one day last week. Only fifty inches was started, and it seems that the workmen expected several hursts, as such a length of pipe is certain to have weak places in it. It had only hurst twice, at last accounts, and the managers were sanguine of the most complete success. It is thought best to wait for the freezing weather to end before turning in the water again.

SAN MATEO COUNTY.

COAL.—San Mateo Times, Jan. 9: Prof. Heruch, the mining expert, in company with J. O. Maynard visited the tunnel on the San Mateo and Half Moon Bay toll-road on Wednesday, and made an examination of the coal measures which Mr. Maynard has been prospecting. The indications are said to be extremely favorable, so much so that arrange-

ments will shortly be made to prospect the measure by means of boring. The principal obstacle hitherto has been water, in itself a favorable indication, and this will be avoided by boring.

SIERRA COUNTY.

STAUKE IT ROCK.—Mountain Messenger, Jan. 9: The boys at Bunker hill, Little Grizzly, have at last run through the "big rock," and sunk down 17 feet into a fine bed of blue gravel, said to be very rich.

The Sierra Buttes and Independence mines are as prolific as ever of the yellow ore, and the numerous ledges around the town promise a rich strike any day. All in all this mining district is one of the most promising in the county.

FOREST CITY was never better. The two prospecting tunnels are being run, the North and South fork have made good headway recently, "and every prospect pleases."

The Empire mining claim at Howland Flat, is paying finely, say report.

Miners are beginning to find fault with the fine weather on account of the scarcity of water in the foreshadows.

NEGOTIATIONS are in progress for the sale of the American company's claims at Morristown. It is one of the best mines in the county.

SCALES DISCOVER.—The miners are busy at work running powder drifts and tunnels. Water for hydraulic purposes has long since ceased, and from all appearances it will be a long time before there will be any more. Owners of mines say naught, but like the Dutchman's boy, think considerably.

TRINITY COUNTY.

IMPORTANT TRANSACTION.—Trinity Journal, Jan. 9: The Bullychoop quartz mine is bonded to a San Francisco company for \$60,000. Of this amount \$10,000 is to be paid before any work is done on the ledge. The company is to erect a mill and other works, which, if the property is not satisfactory, can be turned over to the original company. A wagon road is to be built to the mine next spring.

TUOLUMNE COUNTY.

THE MARKS AND DARROW.—This mine, situated between the Raw Hide and Patterson, is to be developed as fast as possible. Work has already commenced, and the Superintendent, G. P. Fisher, is confident of its proving one of the best mines in the county. A main working-shaft will be put down to strike the vein 50 feet below the surface at the shaft. From this a level will be run north, and as the hill rises very abruptly, a short distance will carry the tunnel 300 feet beneath the croppings, exposing enough ore, by stopping, to supply milling machinery for some time to come, and while the work of further development still goes on.

NEW ALBANY.—Sonoma Democrat, Jan. 9: A few days since the workmen in this mine ran into a vein of rock; samples of which we have seen; they are profusely filled with metal, gold being visible to the naked eye plentifully. This body of ore is reported seven feet wide where the samples were taken from, and gives a future prospect that must be very gratifying to the owners.

Nevada.

WASHOE DISTRICT.

CONSOLIDATED VIRGINIA.—Gold Hill News, Jan. 7: Daily yield, 400 tons, from 1550, 1500, 1400 and 1300-ft level. At the 1550-ft level, good progress is being made in the winze being sunk 300 feet from the northern boundary. It is now over 100 ft deep in very high grade ore. The main north and south drift at this level has passed through into the California ground 35 ft, and the face is still in high grade ore. The last 400 feet of this drift, northward, has no poor ore in it. The east cross-cut, at this level (the 1550) 300 ft from the northern boundary is in 65 ft from the main north and south drift, all the way very high grade ore, and the face shows still higher grade ore. At the 1500-ft level, the cross-cuts east, continue in high grade ore, and have not yet reached the east wall. Cross-cut No. 2, which is the most advanced, is now in over 300 ft in excellent ore, and has not yet reached the east wall. This cross-cut is 130 ft from the northern boundary line. Cross-cut No. 1, 14 feet from the northern boundary line is now in considerably over 100 ft, in the richest kind of ore. At the 1400 ft level, the ore breasts are looking splendidly, and the north drift, which is far in advance of the ore breasts, continues in fine ore, and is yet over 200 ft from the northern boundary line. The width of the ore at this point is as yet unknown. The ore breasts at the 1300-ft level also continue looking and yielding finely.

CALIFORNIA.—At the 1550-ft level the main north drift, from the Gould & Curry has penetrated this mine a distance of 35 ft, passing through very high grade ore. At the 1500-ft level, cross cut No. 3 east, 200 ft from the southern boundary, has penetrated the ore about 8 feet. The ore is of the same rich character as that found in cross-cut No. 1 at the southern boundary. Cross-cut No. 2, 100 feet from the southern boundary, is in a distance of 70 ft, and is expected to reach the ore vein in a further distance of 40 ft. At the 1400-ft level, cross-cut No. 1, 200 ft from the southern boundary has penetrated the ore a distance of ten feet. The ore assays from \$200 to \$350 to the ton. A cross-cut east at the 1300-ft level, directly above that last mentioned, was commenced yesterday to run for the ore body. It will have to run 200 feet to reach it.

UTAH.—The work of grading for the new pumping machinery is well advanced. On the 400-ft level the north drift has been extended

14 ft into the vein and looks favorable.

LADY BAXAN.—New shaft 389 ft in depth. The various cross-cuts for the ledge and also to connect with the old workings of the mine are getting along finely. The ledge is very wide, probably 300 ft and some very rich bunches of ore have been found in its former workings.

CHOLLAR-PORTOS.—Daily yield 35 to 40 tons, from old upper workings. The average assays from car samples is \$25, the quality of ore yielded not being quite so good as heretofore. The ore sections show no change for the better.

OPHIA.—Daily yield 250 tons from the 1465 and 1300-ft levels, and the stopes and floors between. The average richness of this product is constantly increasing, giving better bullion returns. At these two important levels the ore bodies both east and west are looking and promising splendidly, and the north winze below the 1465-ft level is now down about 30 ft in very rich ore which shows still richer as the winze penetrates deeper into it. Ore of extraordinary richness is found in the cross-cuts from the bottom of the winze below this level, near the California line. The other prospecting and developments are progressing finely and most auspiciously under the best of management. From what is seen and developed of the great bonanza in this mine, it evidently bears to the north and east, and the Ophir will get a very good slice of it. It may even extend entirely across it into the Mexican.

BELOHEA.—Daily yield 450 tons. The old ore section, from the 1400-ft level up, are holding out pretty well, with no new ore developments, however in any direction.

GOULD & CURRY.—The double winze sunk from the 1500-ft level, has attained a depth of 268 ft below that point. The work in this winze is being vigorously prosecuted in order to connect sooner with the 1700-ft level, and thereby enable the company to cross-out the vein and develop the lower level.

JUSTICE.—The powerful and costly new hoisting and pumping machinery was started up for trial last Monday for the first time, and operated finely.

BEST & BELOHEA.—On the 1500-ft level the double winze has been sunk to a depth of 268 ft below it. This level will soon connect with the 1700-ft level drift, and the company is pushing the work in this winze with great energy.

PHIL SHERIDAN.—Main west drift in 195 ft to day. Over half the face is in very promising quartz; and the rest in dark clay and quartz.

OCCIDENTAL.—The extensive body of ore exposed by the several cross-cuts contains sufficient metal to be remunerative when actively worked, and at present looks very favorable.

CROWN POINT.—Daily yield, 550 tons. The old ore producing sections from the 900-ft level down, continue to give forth their regular yield, and will hold out for a long time yet, and some is coming from the 1500-ft level.

MEXICAN.—The drift from the 1465-ft level of the Ophir has advanced to within about 30 ft of the south line of the Mexican, and shows a small streak of good ore, which is considered encouraging.

SIERRA NEVADA.—Sinking the new shaft is progressing at a lively rate in favorable material. The machinery at the old shaft is being repaired and put in good order; the requisite repairs to the timbering of the shaft is being done preparatory to sinking 100 ft deeper, giving a total depth to the shaft of 800 ft.

HALE & NONOCROSS.—Daily yield about 100 tons from the old upper workings of the mine.

JULIA.—The main north drift at the 1900-ft level is being advanced at the rate of three ft per day.

GLOBE CONSOLIDATED.—In the face of the west drift at the 400-ft level, the character of the rock is changing fast for the better.

WOODVILLE.—New shaft down 78 ft. The ore stopes south in the 200 and 300-ft levels, are looking better than at our last report.

ANNES.—This mine, which lies directly west of the Consolidated Virginia and California mines, and adjoins the old Mexican mine on the south, is located on a west ledge, which from the present good showing bids fair to develop a bonanza of ore that will rival that of its neighbors. Ore heretofore thrown aside as waste, is now found to assay \$46 to the ton. A fine large body of black sulphuret ore is developed in this mine.

DAYTON.—The third compartment of the shaft is completed, and the total depth of the mine is 330 feet. Sinking deeper is now about being resumed. No change to report in the ore sections. Daily yield of ore, 60 tons. The amount of ore extracted in December was 1,755 tons. Amount shipped to Woodworth mill for reduction, 1,755 tons. Average car samples assay, silver, \$7.10; gold, \$34.96; total \$42.06.

NEVADA.—A fine showing of ore is developed in the old upper workings of this mine, there being a large chimney of it. This is not high-grade ore, but will pay well for milling.

ROCK ISLAND.—Sinking the main shaft goes on vigorously, and the winze below the 200-ft level has been giving a better showing in the way of good little bunches and spots of ore the last few days.

DANEY.—The face of the north drift at the 400-ft level is in low grade ore which shows considerable improvement.

SUCCESS.—The main drift at the 550-ft level is to-day in 105 ft., with its face in very encouraging vein matter, including considerable quartz. The ledge is evidently near by. The shaft is down 536 feet, or 45 ft below the 550-ft level.

Panamint—What "The Company" is Doing.

The Panamint News says: The Surprise Valley Mill and Water company, H. A. Jones, General Superintendent, Capt. James Messie, Manager, is invariably known as "The Company," and doubtless always will be known as THE Company, on account of its gigantic operations, although dozens of other companies may be operating at the same time. To give some idea, though by no means complete, of what the company is doing at the present time, we will state that work is being actively prosecuted on the following mines: Hudson River, Harrison, Alabama, Hemlock and Wyoming, all on the south side of town, and on the Jacobs' and Stewart's Wonders, on the north side. Several of these, particularly the Wyoming and the Wonders, are being attacked by shaft and tunnel in four or five places each. Not one but what is yielding splendidly, and have large piles of good ore on each dump. Good trails or narrow roads have been blasted out at great expense to all; these trails are from one to three miles in length; most of them have been cut to a grade suitable for tramway. At present the ore (all shipping or sack ore) from the Wyoming is brought down upon strong iron-shod sleds, each drawn by a powerful mule, and each bringing three loads a day of about eleven hundred pounds each; six of these sleds are in use at this mine, but numbers of others are being made ready as fast as possible. Two fine rock-breakers, driven by steam, are engaged a good share of the time upon ores from this and the Jacobs' Wonder. Before breaking, the ore is sorted, the second quality being piled up for concentration here as soon as the mills are ready for work, the best quality being broken up fine and sacked for shipment. Forty tons of this class of ore was shipped during the last three days from the breaker at the upper end of town, and there are about sixty tons of the same sort ready for shipment. The average shipment from the Wyoming is nearly ten tons per day of sack ore. The foundation for the twenty stamp mill, with four Krom concentrators, is about ready for the masonry, but owing to the frosty nights this portion of the work may be delayed a short time. The warehouse is ready for the metallic roof; it is sixty feet square inside, with stone walls three feet thick. The present large canvas store is soon to give way to one of wood, still larger. The company ran four boarding houses, and we are told furnish good "grub." They have stabling in the course of erection for about two hundred animals. The whole number of employees is a little over 250. They have one mill complete and ready to run as soon as the pump to supply it with water arrives and is put in place, which will require not to exceed five days from date, the pump being due to-day. They have good second class ore on hand, or easily attainable, to keep one hundred stamps in constant operation, together with a corresponding number of concentrators. They will make this an exceedingly lively camp in a very few months, as they will need at least one thousand men when all their works are in full blast. There is one other thing worthy of especial mention as regards the management of this company. That is, they have taken every possible precaution to obtain perfect and undisputed titles to every mine in their possession or claimed by them. They have undertaken huge work, taken altogether, and are managing it well. They are worthy of success, and we have not the slightest doubt they will attain it, and in so doing effect wonders for the welfare of Inyo county generally.

The Belmont Courier tells of a settlement made by the men lately working for the Morey Mill company. The company failing to pay, the men demanded the delivery of a lot of bullion on hand, belonging to the Morey Mining company. This was at first refused, but the men finally got away with the bullion, and took it to Belmont and sold it—paying themselves with the proceeds, 80 per cent. of their demands.

Rich mineral discoveries are reported near San Fernando, Los Angeles county. A man named Slater has discovered within five miles of the town a silver ledge of some richness. Several finely prospecting gold ledges have been found in the same vicinity; also a cinabar mine of apparent richness. Coal is also reported to exist in the same vicinity.

Or coal from a mine in Shaeta county the Sacramento Union says: "It is a superior article, equal to, if not better, than any other found in the State; it is of a glossy black, heavy and apparently free from sulphur."

The Big Bonanza.

The Enterprise of the 6th instant says: The cross-cut 200 feet north of the south line of the California, on the 1400-foot level has reached the big bonanza, and penetrated it to the distance of five or six feet. They reached the ore evening before last, and already the rock in the face of the cross-cut will go \$300 per ton. The ore was reached much sooner than was anticipated, which shows that the west wall did not bear so much to the eastward as it seemed to do when cut across in the Consolidated Virginia. It is now demonstrated that from the north line of the mine last named the west wall gradually curves back to the west. This being the case, and the east well still bearing to the east, it would seem that we have as yet by no means seen the "bulge" of the bonanza. That grand center of interest—the "bulge"—is crowded still further north. Something is now known of the west side of the bonanza, but the east side is still widening away into the unexplored regions. The cross-cut 200 feet north of the California line, on the 1500-foot level, is also said to have been in ore a distance of two feet yesterday afternoon—much sooner than was expected—though its face has been showing much quartz for some days. The mine was visited yesterday afternoon by Captain Taylor,

are stowed away, and at the Eureka Consolidated 75,000 bushels, while enough is being received to supply the daily demand, averaging 1,500 bushels to each furnace in operation. The product and shipments for the month of December, 1874, were as follows:

DECEMBER.		
Furnaces.	Product.	Shipment.
Richmond.....	1,300,000	831,000
Eureka Consolidated....	784,744	775,284
K. E.....	260,000	287,000
Hoosac.....	221,000	251,000
Total pounds.....	2,565,744	2,114,284

Peavine.

This mining district is so near to us, says the Truckee Republican, that we cannot do better than devote a portion of our space to what is now being done to develop the interests there. Should this district prove to be as rich as all indications now promise, it will be an important market for our lumber and wood. From Mr. B. Johnson, of Reno, who called at our office yesterday, we were able to learn the following items of interest: The prospects in the mines there have been improving greatly within a short time past, and are now much better than ever before. A consolidation has been effected between the Paymaster and Poe mines under

State, Golden Fleece, Buckeye, Nellie Grant and others, all watching with great interest the result of the coming experiment at the Consolidated Poe. There are already between twelve and twenty families already located there, and 300 men employed and no idle men. The city supports a store, a livery stable and three hotels. Since Thanksgiving eight houses have been built. Stages leave daily from Reno at 9 A. M. and arrive at 3 P. M. The place is called Poe City in preference to Peavine in honor of the company. The indications at this place are said to be better than those at Virginia city at the same stage of development and some venture to predict another great bonanza.

Bee-Hunting.

The large illustration which we give on the first page of this, our holiday sheet, is descriptive of one of the notable incidents of country life, namely, bee-hunting. Although bee-hunters in their reports of these adventures generally report satisfactory returns in honey, they almost invariably dwell most on the pleasurable excitement attending the hunt.

The programme of the bee-hunt varies somewhat in different localities.

A very common mode, and one which we will suppose is being used by the parties in the accompanying picture, is as follows: The hunters resort in the daytime to localities where these wild swarms are supposed to exist, and endeavor to entice the bees away from their tree-hives. A common method to accomplish this purpose is to create a strong but agreeable odor, by filling the cells of old honey combs with eniseed and burning it between heated iron or stones. This attracts the bees, and in the vicinity of these enticing fumes, honey or some other bee food is placed. The bees feed on this.

"Which pillage, they with merry march bring home
To the tent regal of their Emperor!"

The hunters follow them in their flight and thus ascertain their retreats. At night they repair to the detected hiding place, provided with axes, torches and vessels for transporting their sweet treasures to their homes.

We see them in the picture after the tree has been "felled," removing the honey from the mammoth hive, or rude city of hives. The full moon is affording all the assistance she can under—or rather over—the circumstances, but the additional light of their pine torches is needed. Two or three hundred pounds of honey is not an unusual yield from one of the bee trees. It happens sometimes that there is a

large amount of old comb in the tree; the quality of the honey being injured thereby, and sometimes too the honey is badly broken up by the breaking or jarring of the falling tree; but in many cases the stock is equal in every respect to the best hive honey, and is removed in good marketable condition.

THE CARSON MINT employs a force of 73 persons. It coins about \$300,000 in gold per month, and about \$200,000 in silver. The silver coinage has recently been confined to trade dollars, of which \$50,000 were delivered to-day, and about \$240,000 within the last month. Superintendent Crawford and Coiner Doane and the other officers state that the capacity of the mint is hardly half so large as it should be. Since its operations have become so extensive and important it is found to be crowded in every department. The Congressional delegation from Nevada is being urged to secure an appropriation for the enlargement and improvement of the building. The sum needed for the work is about \$250,000.

NEW DITCH.—A company of capitalists, John Thomas, agent, will, as soon as the weather will warrant, commence the construction of a large ditch to convey water for mining, from the lakes in the vicinity of Gold Lake to the northern portion of the county. It will be a canal rather than a ditch, and capable of carrying at least 20,000 inches of water. The ditch will probably be 25 or 30 miles long and will furnish a full head of water the year round.—Downieville Messenger.

WELLS, FARGO & Co. shipped for the Manhattan company, of Anet, during the month ending December 31st, ninety-one bars of bullion, weighing 9,228 pounds, and valued at \$116,673.38.

The new pumping machinery for the Utah mine, on the Comstock, is being made in this city. It will equal in capacity and strength any similar machinery on the Comstock.

BEE HUNTING.

Superintendent of the Yellow Jacket, Mr. P. Deidesheimer, the well-known expert, Oscar G. Sawyer, correspondent of the New York Herald, Mr. Channey Lend, mill man, formerly of the Land mill, Seven-mile cañon, and by several other gentlemen taking an interest in mining matters, and all came to the surface perfectly stunned with the wealth seen by them during their underground travels. The only place where the bonanza has yet been crossed is at the south end, where cross-cut No. 3 passes through it. At this point they are beginning to breast out, and the breasts are opening into ore of wonderful richness, disclosing much of that character of ore known as "stephanite." While below the foreman of the mine dug out and presented to Mr. Land a lump of this ore weighing about ten pounds. It was a beautiful specimen, and on reaching the surface Captain Taylor offered Mr. Land \$20 for it, an offer which was promptly refused. We asked Mr. Taylor why he did not take a pick and dig out a specimen for himself. "Well," said he, "I thought it would look a little too much like digging into a man's safe." Mr. Sawyer says that if he writes the Herald a full account of what he saw they will think him the biggest liar on this side of the Rocky mountains. The grand developments in the California were everywhere the subject of conversation on the streets and in the saloons yesterday afternoon and last evening. On the 1550-foot level the main drift north from the Gould and Curry has passed through into California ground a number of feet and is still in the same very rich ore through which it passed for such a great distance in the Consolidated Virginia.

EUREKA BULLION.—The Eureka Sentinel says: The amount of bullion produced at the furnaces for the month of December far exceeds the figures of the same month of 1873. This is owing to the favorable condition of the weather, the easy transportation of ore from the mines and the abundant amount of charcoal being brought to the furnaces. At the Richmond over 200,000 bushels of charcoal

the name of the Consolidated Poe. This company are now having a furnace built, and expect to have it in operation Friday of this week. This is built by Mr. McGlew who is given \$500 and takes the balance from the results of the experiment. The furnace is built at an expense of about \$5,000. The company have already about 350 tons of rock on the dump pile awaiting the completion of the furnace. This rock has been assayed. Twelve assays from the dump were shown our informant, which averaged from \$42 to \$108 per ton. As soon as this furnace is completed and this rock worked a reliable test will be obtained, and calculations can be made with great probability of their being accurate whether it will be advantageous to continue developments in this district or not. The other companies are equally interested in the coming test, for in the event of this amount of rock paying according to the assay, they will have sufficient encouragement to put in capital enough to develop them all. There are croppings along the road between Reno and Peavine, where, in a thousand places prospects have been made with indications enough to induce further outlay of money in the event of success at the Consolidated Poe. The stock of this company is divided into 60,000 shares which have a market value of about \$3—30,000 shares are held by Mayor Brown, of St. Louis, Mo., 17,000 by the Bank of California, as collateral, it is said, and the remaining 13,000 by other men, many of them those that are at work developing the mine. There is a difficulty in working the rock from this mine, on account of the presence of antimony and iron which are separated with some difficulty. The rock after being milled, has to be roasted before it can be amalgamated. This difficulty seems to grow less as a greater depth is reached. This difficulty seems to grow less as greater depth is reached. Our informant went down to the 100-foot level and found the ledge three feet in thickness and well defined. They have reached a depth of 175 feet with increasing prospects. Besides the Consolidated Poe there are the Nevada

GOOD HEALTH.

Fatal Effects of Filth.

X. A. Willard in a late address before the Connecticut Farmers' Convention discoursed as follows:—Many cases of fever have been traced to the consumption of swill milk; diseases have been traced to the milk drawn from cows by the attendants of sick persons; also to the impure water with which milk-pans were washed. Cows that drink impure water give a wholesome milk. Milk becomes impure from particles of dust falling from the cow's udder, which has been gathered by passing through sloughs or mud-holes. Farmers do not as a rule appreciate this matter, but if they in dispose of their milk or butter before any great change is effected, they think all responsibility is off their shoulders. The fine character of English cheese may be attributed to great care in all the operations, running from the conditions of the pasture, as to the cleanliness of the milking-houses, through the stable, the milking-house, washing of pans, etc., to the production of the cheese. Cesspools or dead animals found upon the premises of English farmers are subjects for prosecution.

Putrid water is often the only kind by which a cow can slake her thirst, and yet it is productive of disease. We have a law to prevent watering milk, and yet a farmer is allowed to permit his cows to quench their thirst in the most filthy and poisonous water. Which is the most deserving of punishment? A case of anthrax in a family was traced to the milk obtained from a cow confined in a stable without proper ventilation. While the cow is under a violent excitement, or in an exceedingly nervous condition, the milk becomes highly poisonous, as many cases have abundantly proved. A child fed from the milk of a cow that drank from water oozing out of a hog-pen was covered with sores and pustules. Every factory or milk should have a schedule of questions for its patrons, covering the whole ground of cleanliness, treatment of the animal under all conditions, while in the pasture, at the stable, in their passage from one to the other; condition of pasturage as regards grass, etc., and every direction affecting the product of milk.

Deaths from Lamp Explosions.

There are so many circumstances under which accidents, more or less severe and often fatal, occur from lamp explosions, that people ought not to be too studious in informing themselves with regard to such accidents, or too careful in seeking to avoid them. But a few days since the following case occurred at the house of a friend on Perry street, in this city. A gentleman entered a room late at night in which a kerosene lamp had been burning low through the evening, stepped towards it and was in the act of extending his hand to turn it down, and just before his fingers reached the thumb-screw the lamp exploded with a loud report which sent it in fragments to every part of the room. Fortunately there was no fire set and no person injured. The next morning a careful examination of the fragments to learn the cause of the explosion led to the theory that the tube, which was rather a large one, had been fitted with a very small wick, thus leaving a large air space by means of which, in all probability, the movement of the air in the room, caused by the opening of the door, forced the small, flickering flame down into the tube far enough to communicate with and explode the gas which would naturally, under the circumstances, have accumulated therein.

In this connection it may be interesting, as well as useful, to call to mind the fact that Prof. Chandler, of New York city, says: "The fatal result for the year 1869, for the city of New York, which I myself have cut from newspapers, is fifty-two fatal accidents from dangerous kerosene, fifty severe and six slight—in all one hundred and eight persons, to my knowledge, from my own reading, have been injured by kerosene in one year."

EFFECT OF WARMTH IN PREVENTING DEATH FROM CHLORAL.—Dr. Brunton (who, by the way, has succeeded the lamented Anstie as editor of that excellent medical journal, *The Practitioner*) confirms the observations of Liebreich and others, and finds that the subcutaneous injection of a solution of chloral induces sleep, which is light and easily broken if the dose be small, but passes into coma if the dose be large. In dogs, considerable restlessness was observed before sleep came on, and the respiration was at first rendered rapid but subsequently became slow. A remarkable diminution of temperature was observed, which appears to be partly due to greater loss from the surface, caused by the vessels of the skin becoming much dilated under the influence of the drug, and allowing the blood to be cooled more readily by a low external temperature. It is partly due also to the diminished production of heat, which cessation of muscular action always induces. Dr. Brunton found that an animal wrapped in cotton-wool may recover perfectly from a dose of chloral which is sufficient to kill it when exposed to the cooling action of the air, and that recovery from the narcotic action is much quicker when the temperature is maintained in this way, and still more rapid when the animal is placed in a warm bath, providing this is not excessive. The

bearing of these experiments on the treatment of persons suffering from an overdose of chloral is obvious. The patient should be put to bed, and the temperature of the body maintained by warm blankets and hot-water bottles applied to various parts of the body, especially the cardiac region. Warmth over the heart is an excellent stimulant to the circulation, which, like the respiration, is enfeebled by chloral. If respiration threatens to fail, it should be maintained artificially so as to allow time for the chloral to be excreted and the normal functions to be restored.

COLIC IN YOUNG CHILDREN.—Put a lump of assafetida, about as large as a hazel nut in a three ounce vial, one teaspoonful of magnesia, and two or three teaspoonfuls of whisky, to preserve it; then fill up the vial with soft water. About the time the child begins to cry with the colic give of the mixture from half to a teaspoonful, according to age, diluted in water and well sweetened with white or lump sugar. One dose is generally sufficient to relieve the little sufferer; but if necessary, repeat after a time. It may be unpleasant at first, but the patient will soon learn to like it. This acts on the bowels sufficient to keep them regular. Cordials and soothing syrups are usually astringent—just what a child does not want.

Eat but three times a day, at regular periods, and see that at least a five hours' interval occurs between each two meals.

USEFUL INFORMATION.

Black-Leading Iron.

In these days of general diffusion of chemical knowledge it is scarcely necessary to state that the "black lead" or "plumbago" of commerce, is not lead at all, or any compound of its composition. Neither is it a carburet of lead, and that it includes no lead whatever in iron, as is sometimes stated. It is simply carbon. Pure plumbago is pure carbon, impure plumbago is impure carbon. Its proper name is graphite, that is, writing stone. We may venture to describe it as the softest of all true solids, and have often pondered wonderingly upon the apparently unnoticed, but very curious chemico-mechanical paradox that the hardest and softest of all the solids existing upon the earth are, chemically speaking, the same substance, graphite and the diamond being both carbon.

It is this wonderful softness, combined with persistent solidity, that enables us to smear it over any other solid surface, and thus obtain a solid paint, all body and no medium. For the class of castings to which it is commonly applied where its application can be readily repeated and where it is not exposed to the direct action of water it is unrivalled as a protecting film for iron. Its chemical action, so far as it does act when cold, is reducing, or anti-oxidizing. Its color and tone are so similar to iron that Mr. Ruskin himself could scarcely make any aesthetic objection to its use, and the film is so marvelously thin that it obliterates nothing. There does not appear to have ever been any attempt to estimate the thickness of a well brushed film of graphite, but it would seem that if a hundred strata of such films could be piled in contact with each other, their combined thickness would fall short of that of the thinnest gold leaf.

CHEAP TELEGRAPHY.—President Orton's report of the affairs of the Western Union Telegraph company is calculated to inspire much hope in those who believe that the Government can run the lines at cheaper rates to the public. On the first of January, 1873, a reduction of more than 50 per cent. was made in the maximum tariff between the most remote points on the company's line. This, though occasioning a temporary loss of revenue, has resulted, during the last few months, in a large increase. The reduction was from \$7.50 and \$5 to \$2.50. President Orton now adds that, owing to Messrs. Edison's and Prescott's quadruplex apparatus, which is, at the present time, working successfully between Chicago and New York, and by which two messages are sent in the same direction and two more in the opposite direction simultaneously on a single wire, he believes it practicable before long to cut rates down still lower, and ultimately to establish but four rates for day messages, namely, twenty-five, fifty, seventy-five cents, and one dollar, with half charges (except for the lowest) for night messages.

TO REMOVE NITRIC ACID SPOTS.—The yellow spots produced by nitric acid may be removed from brown or black woolen goods, while fresh, by repeatedly dipping them into a concentrated solution of permanganate of potassa and then washing them with water. The yellow spots on the hands may be removed in the same way, the brown stain produced by the permanganate being removed by an aqueous solution of sulphurous acid.

The United States is now paying over \$100,000,000 per annum for freight and passage on foreign ships, to be carried abroad and expended in the employment and support of other peoples beyond a fair percentage of what should go to foreign vessels, estimating on the tonnage and travel of each respectively.

GREEN wood can be easily finished by scorching the piece after it is shaped out. A few lighted shavings will suffice.

Guns Discharged Without Caps.

It seems almost impossible that a gun should be discharged without the presence of either cap or flint; yet a well authenticated case of the kind seems to have occurred, recently, near Napa, as narrated by the *Register* of that place. It seems that Benjamin Berger, being out with some companions duck shooting, had just fired one barrel, and hearing the shot loose in the other, turned up the gun into his left hand to pour out the charge, taking the precaution to first remove the cap. Notwithstanding the absence of the cap, the gun went off and made a bad wound in his left hand. It seems almost incredible that a gun could be discharged after the cap is removed, but the phenomenon is accounted for by experts on the hypothesis that the percussive quality of the cap had—the weather being damp—adhered to the nipple of the gun and been sufficient to explode it on being jarred incident to shaking the charge out, the hammer being down. That this theory is a correct one, is confirmed by a similar accident which occurred a few days previous to one of the Asylum apprentices, who had been shooting, and having both charges left in his gun, thought to save them by leaving them in till next day, when he would go out again. To this end he removed both caps, let one hammer down carefully, and was lowering the other, when it slipped from his thumb on to the nipple, and discharged the barrel. The other barrel went off at the same instant, as is supposed, by the shock of the first one—both discharging their contents up through the roof. The youth had a narrow escape, and the two accidents confirm the theory of the total depravity of guns, "dangerous without either lock, stock or barrel," because a man once whipped his wife to death with a ramrod."

INSECT ANATOMY.—Dr. R. U. Peper, the naturalist, in giving an account of some microscopic investigations, in which he has recently been engaged, says: I have managed to make a very careful dissection of the tongue of a house fly, and now I can show the so-called *tracheae* on the tip of the tongue very neatly dissected by my own hand. I can also show a very fine specimen of a parasite from a *blowing fly*, with all its organs perfect. I have noticed what I think is a fact that the flies which survive the winter are all, or nearly all, perhaps females; and have just dissected a house-fly, in which I find 106 eggs. I have also demonstrated what is, perhaps, an ontological discovery—that the central lancet of the horse-fly is tubular. For what reason, as he has a snicker from which he draws blood from the wound he makes? The lancet of the horse-fly—the female, for the male has no biting organs, is a compound instrument. When closed it presents a point; when open it shows several points radiating from its base. The two outside lancets have rows of teeth, like those on the jaw of a shark. I suppose the creature introduces the lancet shut, like the sticks of a fan. When it is withdrawn it is opened in the process, and thus makes that ugly tormenting wound which these insects inflict upon horses and cattle. The hollow lancet perhaps carries some kind of fluid to poison the blood or render it more fluid. There is, however, no gland to be found by which this fluid is secreted. That the lancet is hollow, however, I have shown without a question, as I have contrived to make fluid pass through it.

GUM ARABIC.—This useful product came from Morocco, instead of Arabia, as its name would imply. About the middle of November, that is, after the rainy season, a gummy juice exudes spontaneously from the trunk and branches of a species of the acacia in that country. It gradually thickens in the furrow down which it runs, and assumes the form of oval and round drops, about the size of pigeons' eggs, of different colors, as it comes from the red or white gum tree. About the middle of December the Moors encamp on the borders of the forest, and the harvest lasts a full month. The gum is packed in large leather sacks, and transported on the backs of camels and bullocks to the seaports for shipment. The harvest occasion is made one of great rejoicing, and the people for the time being almost live on gum, which is nutritious and fattening. Such is the commercial story of this simple article.

HOW TO USE A GRINDSTONE.—Common grindstone spindles, with a crank at one end, are open to the great objection that the stone will never keep round, because every person is inclined, more or less, to follow the motion of his foot with his hand, which causes the pressure on the same to be unequal. The harder pressure is always applied to the very same part of the stone, and will soon make it uneven, so that it is impossible to grind a tool true. To avoid this, put in place of the crank a small cog-wheel of 13 cogs, to work into the former. The stone will make about .07 of a revolution more than the crank, and the harder pressure of the tool on the stone will change to another place at every turn, and the stone will keep perfectly round if it is a good one. This is a very simple contrivance, but it will be new to many of our readers.—*Cabinet Maker*.

CLEANING OUT-DOOR STATUARY, ETC.—It is recommended, in cleaning moss-covered statuary in gardens, etc., first to kill the vegetation by the application of petroleum or benzine, which will not injure the stone, and to remove it when dry by brushing, finally rubbing with a rag.

DOMESTIC ECONOMY.

Care of Glass and China.

It ought to be taken for granted that all china and glass-ware is well tempered; yet a little careful attention may not be misplaced, even on that point; for though ornamental obnoxious glass-ware is not exposed to the action of hot water in common domestic use, yet it may be injudiciously immersed in it for this purpose of cleaning; and as articles intended solely for ornament may not be so highly annealed as others, without fraudulent negligence on the part of the manufacturers it will be proper never to apply water to when beyond a tepid temperature. But when fractures take place, the best cement, both for strength and invisibility, is that made from mastic. The process, indeed, may be thought tedious; but a sufficient quantity can be made at once to last a life-time. To an ounce of mastic add as much highly rectified spirits of wine as will dissolve it. Soak an ounce of isinglass in water until quite soft; then dissolve it in pure rum or brandy until it forms a strong glue, to which add about a quarter of an ounce of gum ammoniac, well rubbed and mixed. Put the two mixtures together in an earthen vessel over a gentle heat; when well united the mixture may be put into a phial and kept well stopped. When wanted for use the bottle must be set in warm water and the articles to be mended must also be warmed before the cement is applied. The broken surfaces when carefully joined should be kept in close contact for at least twelve hours, after which the fracture will be scarcely perceptible and the adhesion perfect. The broken portion will also be as strong as the unbroken. The same cement may be applied to marble and even to metals.—*English Exchange*.

POISONED BUTCHERS' MEAT.—It is well that all housekeepers, and especially all engaged in furnishing meat for the table should be impressed with the undoubted fact that animals ought not to become excited before they are butchered, because their flesh is injured thereby, and it will spoil quickly. It is frequently the case that some mishap occurs when a hog or a fat steer is to be butchered, or when a hurt is given of great or less moment which puts the animal in deadly fear, and he is likely to break away; in which case men, boys, and dogs give chase, which makes matters decidedly worse, and if, finally, life is taken, it is under pitiable circumstances. There is no doubt that much of the butchers' meat of the large cities is injured by reason of long journeys, inducing a condition of fear and trembling or a high state of nervous excitement which can but effect the flesh. There ought to be special regulations to guard against this in all slaughter-houses, and on farms the utmost care and deliberation should be taken so that butchering may be quickly and successfully performed.—*Dr. Cross*.

ROLLED HERRING.—Herrings having hard roes appear larger and finer fish than those with soft roes; nevertheless the latter are to be preferred, as they really have more flesh and are more delicate. Having scraped the fish, cut off the heads, split open, cleanse and take out the roes. Take the herring in the left hand, and with the thumb and finger of the right press the back bone to loosen it, then lay the fish flat on the board and draw out the bone; it will come out whole, leaving none behind. Sprinkle the herring with pepper, salt and a little chopped green parsley; lay on the soft roe, roll up tightly, leaving the fin and tail outwards, and bind round with a piece of tape to keep it in shape. Have ready some water well seasoned with pepper, salt and vinegar, and when it boils put in the herring and let it simmer for ten minutes, or until cooked. Serve it with butter, parsley or egg sauce poured over.

ARTIFICIAL CHEESE.—As a successor to artificial butter we have now an article of artificial cheese. The experiment of its manufacture has been made in Tompkins county, New York, it is said with great success; and the theory is simply that skim milk cheese, a food material of little value, may be so improved by the addition of foreign enriching material as to be much more valuable. The cream is therefore taken from milk and made into butter, and the skimmed material is made into cheese by the addition of a pure and wholesome, but cheap oil.

FRIED VEGETABLE MARROW.—Cut the marrow in strips an inch and a half long and three-eighths of an inch square; sprinkle freely with fine salt, and place the strips under an inverted plate in a basin. In a couple of hours put them in a cloth, and thoroughly dry them by wringing them in the cloth; then flour them in the same manner as whitebait, and throw them into plenty of boiling lard. As soon as they begin to take color drain thoroughly, sprinkle with salt and serve hot.

OYSTER OMELET.—Whisk four eggs to a thick froth; then add by degrees one gill of cream; beat them well together; season the eggs with pepper and salt to taste. Have ready one dozen fine oysters, cut them in half, pour the egg into a pan of hot butter, and drop the oysters over it as early as possible. Fry a light brown and serve hot.

TABLE OF CONTENTS.

EDITORIALS AND GENERAL NEWS.—Hydraulic Mining in California; The Ladies' Friend; An Improved Harrow; The Colusa Quicksilver Mines; The New Mint Engine, 33. Big Capitals—Small Profits; Eastern Mining Excitements, 40. North Pacific Coast Railroads; The Carolina Parrot; Quicksilver Mining in Mexico, 41. Grain Elevators; Patents and Inventions; The Blue Hills; The Bribery Investigation; The New Currency Bill, and other Items of News, 44.

ILLUSTRATIONS.—Improved Lap Board; Diagram taken from Engine at the New Mint; Donohue's Improved Harrow, 33. Carolina Parrot, 41.

CORRESPONDENCE.—Among the Quicksilver Mines, 34.

MECHANICAL PROGRESS.—Improvements in Glass Manufacture; Single Rail Steam Towing on the Belgium Canal; India-Rubber Tires; Improved Stucco; Relative Cost of Water and Steam Powers; A New Wonder in Steam; A New Paper Board; Immense Photographs; Paper Manufacture, 35.

SCIENTIFIC PROGRESS.—A New Bleaching Material; Phenomena in Iron Mining; Scientific Discoveries in Cyprus; Improved Chromo-Lithographic Process; Electro-Magnets for Blasting; Electricity and Muscular Action; Sunspot and Ozone; The Great Telescopes; New Discoveries in the Mammoth Cave; Science Proving its Fruits; Irregularity in the Earth's Rotation; Spontaneous Combustion, 35.

MINING STOCK MARKET.—Thursday's Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of Stock Market for the Week, 36.

MINING SUMMARY.—From various counties in California and Nevada, 37.

GOOD HEALTH.—Fatal Effects of Filth; Deaths from Lamp Explosions; Effect of Warath in Preventing Death from Cholera; Colic in Young Children, 39.

USEFUL INFORMATION.—Black-Leading Iron; Cheap Telegraphy; To Remove Nitric Acid Spots; Guns Discharged Without Caps; Insect Anatomy; Gum Arabic; How to Use a Grindstone; Cleaning Out-Door Machinery, Etc., 39.

DOMESTIC ECONOMY.—Care of Glass and China; Poisoned Butcher's Meat; Rolled Herring; Artificial Cheese; Fried Vegetable Marrow; Oyster Cmelette, 39.

MISCELLANEOUS.—The Sumner Mine; All Alive to the Northward; The Sheep Ranch Mine; Coal Sales; Ward and Julia; The New Standard Mining; De-Weir; New Locations; Good for the "C" and "C"; Foundrymen Exempt from Licenses; Ore Shipped, 34. Panamint—What "The Company" is Doing; The Big Bonanza; Eureka Bullion; Peavine; Bee-Hunting; New Ditch 38. San Francisco Microscopical Society; The Emma Mining Bubble; Mining Operations in Calaveras County; Quicksilver Production of Colusa County; Encouraging, 42. Steel Shoes and Dies, 44.

Tule Bottle Cover.

Earl K. Cooley, of this city, has recently secured a patent through the MINING AND SCIENTIFIC PRESS Patent Agency, for a machine for making bottle covers out of tule grass. The machine consists of an endless belt, feeding to a clamp a series of lengths of the stalks of the tule grass or other rush, the clamp seizing and holding them until a series of needles with threads, carried upon a sliding frame, puncture them and string them, the thread remaining through the stalks as they are withdrawn. It also consists in hooked claws, operating intermittently and conjointly with the needles to serge the thread and prevent it from being withdrawn by the needles, and in a reciprocating knife operated by the movement of the sliding frame, to cut the threads in proper lengths as the needles recede. The invention and letters patent have been purchased by Ire S. Warring, of this city, to whom all communications can be addressed.

POCKET MAP OF THE COMSTOCK.—We received this week a pocket map of the Comstock lode, showing the latest changes up to Jan. 1st, 1875. It was compiled and drawn by Edward B. Lasalle, Topographical Engineer, room 19, Montgomery block. It is on a scale of 1200 feet to the inch. This little map was one much needed, and that it supplied a demand was proved by the sale of over 500 copies in the first three days. The map shows some 18 or 20 more locations than the other maps of the same region. A list of Washoe stocks in the Stock Boards is given, with the number of feet and shares. The map is a very convenient one, neatly prepared and bound, and, as far as we can see, seems to be correct. It is much cheaper than the large roller maps and answers every purpose as a means of reference.

An asbestos deposit is being worked on the line of the Amador canal, about ten miles above Jackson.

Big Capitals—Small Profits.

Most of the new mining companies recently organized, have been incorporated with capital stock varying from five to fifteen million dollars. Ten millions seems to be the favorite of late, and few promoters think of putting anything before the public at a less amount. Moreover, the mania to increase the capital stock of companies which have been long in existence, prevails to a greater extent than ever before. These companies increase their capitals from one and two million dollars in ten and twenty thousand shares, to five and ten millions divided into from one hundred to five hundred thousand shares. Where all this business will end can not be seen, as there is precisely no limit to the amount the capital stock may be increased on paper. But unfortunately the shares bear a proportion to the capital stock of course, and how numbers of mines which have never paid a dividend on thirty and forty thousand shares can ever pay a respectable one on a hundred or two hundred thousand shares we do not see.

It may be all very well to divide up each mine as the California, Consolidated Virginia, etc., which are supposed to contain countless millions, and the shares of which are held at such enormous prices in consequence; but there is very little real benefit in doing the same thing with dozens of other mines, which are only kept running by the expectation of striking ore.

Taking the Comstock mines for instance, which are listed on the Board: Best & Belcher, with 542 feet in the mine is divided into 100,800 shares; Belcher, with 1,040 feet, has 104,000 shares; Bullion, with 943 feet, has 100,000 shares; California, with 600 feet, has 108,000 shares; Cosmopolitan, with 1,000 feet, has 100,000; Cons. Virginia, with 710 feet, has 108,000; Crown Point, with 600 feet, has 100,000; Dayton, with 1,600 feet, has 100,000; Imperial, with only 180 feet, has 100,000; Kossuth, with 2,800 feet, has 108,000; Leviathan, with 2,000 feet, has 100,000; Mexican, with 600 feet, has 100,800; Ophir, with 675 feet, has 100,800; Silver Central Cons., with 1,500 feet, has 110,000; Sierra Nevada, with 2,640 feet, has 100,000; Whitman, with 1,800 feet, has 100,000 shares. These are the principal ones called on the Board which have more than 50,000 or 60,000 shares. It will of course be noticed that the size of the mine bears no proportion to the number of shares, and that the number of shares is not in proportion to the value of the mine.

When we come to think, however, of mines with a capital stock of \$54,000,000 divided into 540,000 shares, as will be the case with the California and Consolidated Virginia in a few weeks, it is pretty hard to base any calculations about the real value of a share, even if the ground were all pure silver. California, with 600 feet will have a capital stock of \$54,000,000 divided into 540,000 shares. This is 900 shares to a foot, making each share cover a space of ground one seventy-fifth of an inch in thickness. Thus, a man owning one share owns one seventy-fifth of an inch of the mine, and he would have to own 75 shares to own an inch out of 600 feet. With paper of ordinary thickness and each share on a separate certificate, if he set his 75 shares up on edge it would cover all he owned. If these shares sell at only \$5 or \$10 each, the mine will have to be nearly pure silver to pay any respectable dividend on the capital stock for a year. In Consolidated Virginia the buyer will own a little more ground in proportion to the share. It will have the same number of shares, and with 710 feet, will have about 760 shares to the foot, so that each share will represent an ownership of about one sixty-third of an inch in the whole mine.

This is running things pretty close, even for mining ventures; but the examples of these large mines with their immense bonanzas is not one to be followed by ordinary companies. The much maligned Emma and several other American mines owned in England, would have paid a fair profit on a reasonable capital; but when people expect mines to pay what investors expect at least—three per cent. per month—on capitals of from 10,000,000 to 50,000,000, they are unreasonable. The two mines mentioned may be exceptions; and if half what is said is true, probably will prove so; but this is no argument in favor of putting every new mine in the market with a capital stock of such enormous figures that not even the most sanguine buyers expect a fair dividend on the amount, but trust to owning a large number of shares. Times of excitement like the present are just the occasion of these moves, which of course every one knows are only intended as stock-jobbing operations. "Giving poor men a chance" is, however, too thin an excuse to be swallowed by everybody.

The miners about Ukiah, Mendocino county, have organized the Ukiah mining district, electing S. Wrentzen Recorder. The United States general mining laws were adopted. The district starts from Sanel district on the south and runs up the neighborhood of Little Lake.

W. FRANK STEWART has located a valuable claim on Mount Davidson, nine miles from Virginia City.

Eastern Mining Excitements.

What queer ideas they have about mining for gold and silver in the Eastern States. Their heads are very level on coal and iron, but when they find, or think they find, precious metals, they immediately become demented. They hunt up an "old, experienced California miner" who perhaps lived here, or worked in a mining town, and knew nothing of mining, to tell them all about it. If he has been in California, it is enough for them, and his predictions are implicitly believed. Now, not one man in 500 in this State knows anything about practical mining whatever; and nine-tenths of those who have worked in the mines here would not be competent to take charge of one. Very few men are good managers, and still fewer are the experts whose judgment as to the future of a mine may be relied on. Still these Eastern people believe anything the "California miner" tells them, especially if it is favorable.

The latest excitement we have heard of is the discovery of "six miles of silver," at Newburyport, Mass. A man named Rogers found some metal, thought it was valuable, and then studied geology and mineralogy to find out what it was. He kept his secret until he bought the land, in company with a rich farmer, paying \$350 for it. He found float and at six feet struck the "true vein." The Boston Advertiser contains a long account of the matter, which for ignorance of mining is rich, but we have only room for a few extracts:

The pieces taken from the pit, as dug by Mr. Adams, exhibited vein structure, the upper five inches being composed of galena, while the under three inches—the three inches next the supposed foot-wall—contained considerable gray copper ore or tetrahedrite, galena, quartz, copper end iron pyrites. Four specimens were assayed. The first, coarse-grained galena, assayed for silver, yielded \$56.37; and the second, fine grained galena, \$75.23 per ton; the third, a comparatively pure piece of gray copper, containing also some quartz and galena, assayed for silver, copper and incidentally for gold, yielded, of silver, \$1,270 per ton; gold, \$129 per ton; and about 27 per cent. of copper. The fourth specimen, weighing about three pounds, tried for lead, was found to be nearly pure, and hammered quite readily. The lead was 52 per cent. of the whole matter. The mine has been bonded for \$100,000.

The Advertiser then goes on to state that systematic mining operations were commenced by sinking a shaft ten feet square. "As the shaft increased in depth the vein, which is what is known as a fissure vein—that is, metal between two walls of granite, where, in all probability it was thrown by volcanic action—the vein broadened from three feet at the surface to seven feet at present working—twenty-five feet down. As the men descend the vein grows richer and purer, the proportion of silver and gold increasing, while that of the lead remains about the same. The south wall has not yet been reached. The men are therefore working on the pure metal, the north wall being perfectly perpendicular. In consequence of this fact, which is totally without a parallel in mining history, there is but the smallest possible expense incurred in removing the ore—about \$1 per ton. About ten tons are taken out, being hoisted up in buckets every twenty-four hours. To work this quantity only four men are required by day, and a relieving gang of equal number by night. This ore, which is piled in a storehouse, as at present mined, yields \$90 per ton of silver, \$70 of lead, and \$11 of gold; a total of \$171. The cost of smelting and separating is \$20 per ton, so the profit is \$150 per ton. Another shaft has been sunk almost as deep as the other, and they have a four-foot vein. They have out 125 tons of ore."

The Advertiser then gives us some figures, saying \$1,500 per day is pretty good profit, this what they expect; "and this from a single shaft only 25 feet down, without operating the drifts, or lateral veins." Mining experience, however, has demonstrated that a fissure vein is always without bottom. This vein is estimated by geologists to extend in its general direction twenty degrees east of north about six or seven miles in length. Bearing this fact in mind, the wealth to be reasonably expected from this "find" can only be estimated by comparison. The Comstock lode in Nevada, hitherto supposed to be the richest silver mine in the world, yields only \$45 per ton on the average, while that at Newburyport yields just double that. The Mariposa mines, which were sold a few years ago to a company for \$10,000,000, yielded only \$15 per ton of silver. The Belcher mines, in Colorado, which yield about \$40 per ton, divided \$900,000 among the stockholders as the profit of work during the month of August, 1874. And these mines had not the additional profits accruing from the production of lead. A correspondent of the New York Tribune describes the whole thing in nearly the same language, and that experienced Colorado and Nevada miners are going to work them in the Spring.

All this reads like a pretty good joke to us, of course, although they are evidently in earnest there. It is no exaggeration, whatever, to state that, in all probability, there are from one to five ledges per day found on this coast in different localities, but not more than one in fifty amounts to so very much after all. The

"perpendicular foot wall which is without a parallel in mining history," seems to be going to help them out with the ore, in some way not explained. We strongly suspect moreover that the "yield" spoken of is simply assay value, and when greebombs work the ore they will not get even this 60 or 70 per cent. which we obtain here. Any miner can tell what a difference there is in an assay of specimens and average yield of ore. A piece of ore from a mine may assay \$1,000 per ton and perhaps ten tons of ore crushed just as it came from the ledge may not yield \$100 for the whole ten tons. Any one who knows anything about mining will admit that this often happens. To get of any proper figures of such values, a quantity of ore—several tons—should be crushed, sampled by competent persons, and several assays made. The assays being averaged, if this ore then, will assay \$100 per ton they may be able to get from \$60 to \$80 per ton from it, according to the class of ore. These men have probably taken the best specimens for assay and build all their calculations on the result.

The Transcript says: "The Comstock lode, in Nevada hitherto supposed to be the richest silver mine in the world, yields only \$45 per ton on the average, while that at Newburyport yields just double." There is a nut to crack for the Comstockers with their big bonanza. But isn't it just a little rough to class the whole ledge as yielding \$45 per ton and take it for granted that there is only one mine. We do not know exactly how many mines there are on the Comstock, but there are 103 of them in the list of the stock boards in this city and probably several hundred more locations not listed on the boards. Consolidated Virginia and California have recently struck ore some specimens of which assay as high as \$8,000 and \$15,000 per ton, and is expected to average \$200 per ton. Mr. Dedehelme, the expert, estimates that one pillar alone in Consolidated Virginia will yield seventy millions, but the Newburyport mine is expected to excel this.

The Transcript puts the Belcher mine in Colorado instead of on the Comstock and adds that with \$40 rock it paid \$900,000 in dividends in August 1874. Now the Belcher mine only paid \$312,000 in dividends in August but it has paid \$3,504,000 in dividends during 1874. During the June quarter of the year it hoisted 47,020 tons of ore which yielded \$3,599,892, an average of \$80 per ton. The Transcript thinks that the Belcher had not the profit accruing from the additional product of lead. We do not know anything they would want less in the ore than a quantity of lead. The ore could not be milled and would have to be melted which, when fuel is as high as at Virginia, would be very expensive. Our base metal mines have not, as a general thing, been very profitable as yet.

While we cannot blame people ignorant of such matters for getting excited over rock which assays \$171 per ton, it is to be hoped that they will take the experience of other people before putting any money into "mines" of which they know nothing. Few practical miners pay much attention to what ore from a new ledge is supposed to yield, until they see what it actually yields under the stamps. The property at Newburyport is already in litigation as the man from whom the land was first bought says it was obtained from him by fraud. They may find a mine of some value there, but that it will "rival the Comstock" is simply nonsense. We have perhaps on this coast from fifty to a hundred and fifty thousand mining locations, and some of those on the Comstock are ahead of all. A new mine here is a matter of little moment and even this week we chronicle in different parts of this paper eight or ten new discoveries; but until they prove themselves paying mines, but little attention is paid to them except by the owners. We hope our Eastern friends will go slow, and not base calculations of wealth on the assay of a few specimens without taking into consideration average yield, cost of mining, working ore, etc.

They have proved one thing however, which beats us. They have proved, with a 25 ft shaft, that their vein is a true fissure. And they have also beaten us in finding ore which yields 52 per cent. lead, 27 per cent. copper, \$1270 in silver, \$129 in gold, besides the pyrites, etc. There must be very little gangue left to hold it together.

The Nevada Transcript learns that the Pittsburgh mine, owned by County Treasurer Safford and Cook Brothers, on Deadman's Flat, near Grises Valley, very rich rock has been struck. Some of it panned out as high as \$80 to the pan. The prospect is good for the development of a first-class ledge there. Another ledge has also been discovered at the same place. Some men started in to work a few days ago and found a ledge. They took out a lot of quartz and had it crushed; it yielded them \$7 per day to the hand.

The daily yield of ore during the past week from the Crown Point mine has been 550 tons, Belcher 450 tons, Consolidated Virginia 400 tons, Ophir 200 tons, Hale & Norcross 100 tons, making a total daily product of 1,750 tons of ore from the five leading Comstock mines.

"Rich strikes" are becoming remarkably frequent in the State. It is not alone gold and silver which is being brought to light in untold millions, but precious metals and minerals of all descriptions.

All the mining claims in the vicinity of North San Juan, Nevada county, have shut down for want of water.

North Pacific Coast Railroad.

The opening of a new railroad is an important event in almost any country, but in California, where we have, as yet so few roads in operation, it is even more important than in most of the other States of the Union. The State is so large, and our watercourses and rivers so few that railroads are more of a necessity with us than elsewhere; and as the interior is being rapidly settled up, railroads are being projected and built more rapidly than most people suppose. The North Pacific Coast railroad, our principal narrow gauge road, was formally opened on the 7th instant, being finished as far as Tomales, Marin county, 52 miles from Sausalito. This company was incorporated in 1871, with a capital stock of \$1,500,000 which was afterwards increased to \$3,000,000. Being a narrow gauge road the cost was very much less than would have been the case with a track of the ordinary width. From Sausalito to Tomales the distance is 52 miles, including a branch track into San Rafael. The route selected is as follows: Starting from deep water at Sausalito, where the company have constructed a large and commodious wharf, and have located their machine shops and round houses, it skirts for two miles the shore of Richardson's Bay, thence crossing an arm of the same by means of a substantial bridge 4,000 feet in length, now nearly completed. It passes through Marin county via the town of San Rafael, its county seat, to the head of Tomales Bay; thence skirting the shore of that bay to the town of Tomales; thence passing from Marin to Sonoma county, and via the towns of Valley Ford and Freestone, to the Russian River, along the south bank of which the road is located, to the point of crossing, about four miles from its mouth. From this point it follows near the coast of the ocean to the mouth of the Walhalla river, a total distance of 115 miles, the point of crossing the Russian river is 77 miles from Sausalito and 85 miles from San Francisco, and is the terminus of the first division.

The rails of the track are 3 feet apart, and the iron weighs 35 pounds to the yard. Very serious engineering difficulties were encountered, but these were overcome very successfully, at a moderate cost, with easy grades. The highest grade coming from Tomales to San Francisco, which is in the direction of the largest traffic, is 80 feet to the mile; and in the opposite direction the highest grade is 120 feet to the mile. Construction was begun in 1872, and up to the present time \$1,500,000 has been expended. This includes the purchase of the San Quentin ferry steamer, the "Clinton," and the "Contra Costa," and an expenditure of \$70,000 on the line beyond Tomales. One of the most formidable difficulties was the bridging of Richardson's Bay. This structure is 4,000 feet long. So far there are three tunnels. One of these at White's hill is 1250 feet long; another, on this side of White's hill is 200 feet long; and the third near Tomales is 130 feet long. A barge has been built that will convey 18 cars from Sausalito to San Francisco, the real terminus of the road. The present equipment for traffic is six passenger and two baggage cars, very neatly constructed by the Kimball Carriage Company; four locomotives built at Philadelphia by Baldwin & Furley, and seventy-five freight cars with 50 more in course of construction.

The country through which this road passes is a fine one. Most of it is farming and dairying land, until the road reaches Russian river, where it gets into a timber country. The dairy produce from the Point Reyes and Olema sections can all be brought by this road, and the dairying and farming interests of Tomales, Freestone, Bloomfield and Bodega, will be greatly benefited. The harbors on the coast are few and unsafe, and it has been difficult to stop at all times at Tomales. As a consequence farmers about Bloomfield, and that vicinity, have hauled their grain, potatoes, etc., to Petaluma, which is 16 miles from Bloomfield, in preference to hauling to Tomales and sending by sea to this city. All through the section traversed by this railroad they have been waiting patiently for years for a railroad, and the farmers are now naturally jubilant over its partial completion.

It is expected that the road will pay a gross income of at least \$400,000 a year after the first 12 months, and in 1876 they expect a net earning of \$200,000, as a profit on the first division of the road, which will have cost \$1,700,000. The culverts and bridges on the road are of a very substantial character, and the piling in Richardson's and earthworks at Tomales have been done in first-rate order. The curves on the road are laid out in from 8 to 17 degrees, although there is one curve of 20 degrees. In the course of next summer some changes will be made which will reduce a few of the curves and shorten the road slightly. The highest embankment on the road is 70 feet high, and the deepest cut about 40 feet. The depots at stations have not yet been built, but will be during the summer. After the road reaches Russian river it follows it to the coast and thence runs up the edge of the redwoods

of North Sonoma county to Mendocino county. This is the ultimate destination of the road, unless they see their way by that time to stretch out for the northern counties. This summer they will only attempt to reach Russian river, and will be satisfied if they carry out their expectations of getting to Knowlesville by October.

Howard Schnyler's estimate, as stated in the Post, of entire cost of the line to Knowlesville, 77 miles, including full equipment, was \$1,848,600. The actual cost of the road to Tomales, 51 miles, making with the San Rafael branch 53 miles, and the present equipment, is less than \$1,400,000, the other \$100,000 having been more than expended on earth work beyond Tomales, and the purchase of the San Quentin ferry and steamers, which were not included in his estimate. This is just \$26,415 a mile, or say, when the depots are erected and ballasting finished, \$27,000. Compared with the cost of other roads in the State, which had no such en-

Quicksilver Mining in Mexico.

We have received, through the kindness of the Mexican Consul in this city, the following items relative to quicksilver mining in Mexico from Antonio del Castillo, sub-director of the School of Mines in Mexico.

Since the epoch of scarcity of quicksilver, preceding the discovery of Guadalupe and New Almaden in 1840 and 1845 respectively, this article had not reached its present price of \$200 per quintal in Mexico. Suspension of many mills throughout the country is the natural consequence. Now and old deposits of mercury are, however, being brought into notice. Near San Felipe, State of Guanajuato various deposits are being worked, whose yield, however, cannot supply the demand from the State. Near Guadalupe, and Charcos, State of San Luis Potosi, some veins are yielding quicksilver, though not enough

The Carolina Parrot.

The Carolina parrot, or parakeet, shown in the accompanying cut, is the only one of the two hundred species of its genus, which has been found in the United States. It is restricted to the warmer parts, rarely venturing north and east of Virginia, though it visits much higher latitudes in the West. But it is abundant in the regions of its residence, namely, South Carolina, Georgia, Florida, Alabama, Louisiana, and along the Mississippi up to Kentucky.

These parakeets are exceedingly annoying to the farmers, not only in consuming, but in laying waste and destroying their grain in stacks or standing in the field. They also lay waste orchards of pear and apple trees, merely for the seeds, and this often before the fruit is ripe, when they consequently will not eat the seeds. They come in large numbers, and, though they appear to be concerned for the slaughter of their companions, they will not fly away from the deadly weapon which is destroying them; thus hundreds are often slain by the side of a single stack of grain, which they had covered so densely as to appear like a vast green carpet spread over it.

The roosting places of this species are in hollow trees, and the holes excavated by the larger species of wood-peckers. At dusk, a flock may be seen alighting against the trunk of a large sycamore or other trees having a considerable excavation within it. Alighting on the bark beneath this aperture, as many as can crawl into it do so, and the rest attach themselves by claw and bill to the exterior, and here repose throughout the night.

The flight of this bird is rapid and straight, through the forest or over rivers and fields, accompanied by inclinations of the body, which expose to view alternately the upper and under parts. They deviate from a direct course only when impediments occur, when they glide gracefully aside and continue on. They keep up a general cry when on the wing. They circle wide and high over a spot before alighting, and move with facility upon the trees, often in a sideling way; or hang in every imaginable posture. On the ground they are awkward and helpless. They are easily tamed, being subdued by repeated immersions in water. But as they cannot be educated to utter words, as their screams are very discordant, and especially as they are exceedingly destructive, they ought not to be regarded as desirable pets.

Steel Shoes and Dies.

A correspondent of the *Stock Report*, at Virginia City, writes under date of the 2d:

Considerable interest is being taken among mining men now in regard to the new steel shoes and dies recently introduced by the Cast Steel Shoe and Die company of San Francisco, and I have been examining into it a little myself. I saw to-day a battery of five shoes and dies sent to the Rhode Island mill. They were put in on the 2d of December, and have been in constant use until to-day (31 days). The shoes are worn less than one inch, and are very even. The wearing of the dies is scarcely perceptible. The foreman thinks the shoes will last four months yet. At a shop on C street they have on exhibition a die made of steel, which had been used at the Morgan mill continually for four months, and which was still in good condition, to appearances, for more stamping. I visited the Morgan mill also, and Superintendent Hanson informed me that he had used two sets of steel shoes and dies, the shoes lasting four months and the dies six. At 16 cents per pound for steel and 6½ cents for iron, he finds a great percentage in favor of steel, not taking into consideration the great gain in the increased crushing capacity, by reason of the steel wearing more evenly. Mackey & Fair have ordered a sample set for the Sacramento mill, and if they prove successful they will be introduced into every quartz mill on the Comstock.

In view of the mines already discovered and the strong presumption of other good mines in this vicinity, says the *Mendocino Dispatch*, a miners' meeting was held in Ukiah on Thursday last, at which a code of laws to govern mining in the district was adopted, and S. Wurttemberg was elected Recorder.

A SNOW SLIDE occurred near Alta City, Utah, on the 11th inst., burying to the depth of 30 feet four ore teams, and it is feared that five men were killed.

The Union gravel mining company have completed their tunnel to Kennebeck hill, Nevada county, and are taking out gold in large quantities.

The hydraulic works at the Yellow Jacket quicksilver mine, Napa county, are in full operation.

A RICH STRIKE has been made in the south drift of the Consolidated Poe mine, at Peavine.

IRON ore has been found in the mountains east of San Fernando, Los Angeles county.

LYNO claims to be the richest mineral county in California.

CAROLINA PARROT.

engineering difficulties to contend with, this is a most favorable showing.

Though no experiment, this is a sort of test road, and if the average freight and traffic reaches \$8,000, or even \$5,000 a mile per year, it will settle the future gauge of all our local lines. There are in this State hundreds of valleys which will furnish \$5,000 a mile receipts per annum. And in none of these could a costly broad gauge be made to pay even five per cent. interest per annum at any reasonable tariff of charges.

THE Stock Exchange has elected the following officers for the ensuing year: James R. Keene, President; Coll Dean, Vice President; B. Howard Coit, Chairman; Henry Schmiedell, Treasurer; Franklin Lawton, Secretary; and Thomas M. Blair, Sergeant-at-Arms.

J. P. FRIENDLEY has tendered the Willmette Valley and Coast railway a gift of ten acres of ten acres of land adjoining Corvallis for the use of the road as grounds for machine shops, turn table, depot, etc.

THE Salt Lake *Herald* thinks San Francisco and Virginia should erect a monument of silver to Comstock, the discoverer of the Washoe mines.

THE Supto tunnel is in 8,079 feet.

for the same State. In Zacatecas where there exists great demand for quicksilver, one vein has been discovered near Sainetro, though not indicating great richness.

In Durango there are extensive deposits which have been abandoned for upwards of two years, on account of the company's embarrassment and political difficulties. Some poor miners still work around these old workings and obtain a considerable amount of quicksilver which is used by the mines of Sinaloa. Rich specimens come in daily from various sections of unexplored country, promising vast discoveries. At 40 leagues from this city in Guerrero immense deposits have just been discovered bearing two minerals; one containing mercury, sulphur and antimony; the other oxide of antimony, mercury and silicate yielding 10 to 14 per cent. of quicksilver. Furnaces are needed, the present earthen vases being wholly insufficient. There is an old mine near Pregones between Tasco and Zacualpan, 50 leagues from this capital, which since the time of the Spaniards has yielded rich cinnabar. Ore four inches wide yields 70 per cent. in clay containing 10 to 20 per cent. in a well defined ledge connected with a silver-bearing ledge.

By operating the 50 known deposits, Mexico could produce 2,000,000 to 2,500,000 lbs. required for home consumption and probably have some over for export.

San Francisco Microscopical Society.

The regular meeting of the San Francisco Microscopical Society was held on Thursday evening of last week.

The Secretary announced that additions to the library had been made by the purchase of two volumes of "British Diatomaceae" and "Beck's Treatise on the Achromatic Microscope," also, additions to the object cabinet by purchase of 66 slides mounted with various objects, comprising a series of the fatty acids, bone sections, vegetable fibers, diatoms, many miscellaneous objects, and one of J. D. Moller's Diatom Type Plates. One of Nachet's prisms for oblique light with high powers, was announced as having been received, and its capabilities were tested by Mr. Hyde with satisfactory results.

Mr. Hanks donated two slides mounted by him with iodide of mercury, and some specimens of topaz, from Durango, Mexico.

Dr. Blake donated a slide mounted with a section of calcite, prepared by him from a beautiful specimen which he exhibited.

Mr. Ewing donated two slides mounted with spicules of Gorgonia, and section of spine of echinus.

Dr. Harkness donated 18 slides mounted with a fine variety of interesting objects which he had received in exchange from microscopists in Providence, R. I.

Captain John H. Mortimer sent the Society, through Mr. Kinne, a number of vials containing boilings of diatoms and other objects, from 18 different localities in various parts of the world.

Mr. Kinne stated that he had examined the contents and found most of them very rich in varieties of diatoms, polycystina and ferminifera.

Dr. Thornton presented the Society with a number of samples of soundings from Santa Barbara channel.

Dr. Harkness made some interesting statements regarding the fungus found on the scorched willows in San Mateo county, and which he reported on at some length at previous meeting, to the effect that since then he had forwarded the same to Professor Harlow, of Cambridge, and he had identified it as *molaucomis stilbostoma*—Tulane. The Doctor further stated, regarding the nostoc which he had brought before the Society previously, that it had not been identified at either Yale or Harvard, and had been sent to Paris for the opinion of the highest known authority.

The energy displayed in original investigation by many of the members of this Society is attracting attention in other localities, and their membership is increasing rapidly.

Several new proposals for resident membership were received, and the following named gentlemen were elected, having been proposed at a previous meeting, viz.: Mr. Ed. F. Hall, resident; Mr. Eugene Burgoyne, Paris, corresponding; and Dr. H. W. Harkness, honorary member.

The unanimous compliment bestowed on the last named gentleman is a deserving one, the members fully appreciating what he has done as a corresponding member in the way of giving them freely of what information he had obtained in over twenty years' microscopical research.

The Emma Mining Bubble.

For several years past the Little Emma Mining company of Utah has been a by-word in financial circles and a reproach to Americans. Unable to float the enterprise in this market, its promoters went abroad, and in the London market found people eager to jump at the bait. High hopes were entertained, but they were speedily dashed to the ground. The history of the Emma mining scheme has been too often related by Englishmen and no less indignant but shrewd Americans, to need many words here. What now remains to be told, however, is the fact that the victims in England having come to the conclusion that it was useless to waste further effort in lamentations and denunciations, have resolved upon a vigorous prosecution for the recovery of their money. With this object in view, suits have been begun on both sides of the Atlantic. In England a petition has been filed for the purpose of winding up the company. In this city, however, important proceedings have been instituted against the principals in the scheme. Upon the installation of the present Board of Directors, a committee was appointed to come to this country, inspect the property, investigate the affairs of the company, and take such action as might be necessary to secure the rights of the shareholders. General Gardiner, the chairman of the company, and Mr. Turner, his solicitor, undertook the investigation. They came to this country, visited the mines at Utah, and upon their return to New York ordered Shipman, Barlow Laroque and Macfarland to begin a suit against Trenor W. Park, Senator Stewart, of Nevada, and General Baxter for \$5,000,000, the complaint charging fraud and conspiracy.

The law firm learning that Mr. Park, who is the President of the Panama Railroad, and the promoter or owner of a new set of mines in California, was on the point of leaving this city for California, served a summons upon him to answer, and acquired jurisdiction before he had left the city. In deference to Mr. Park's request, however, no further proceedings were taken, as he wished to have his answer ready for publication simultaneously with the complaint. He has just reached San Francisco,

and it is expected that he will be absent only a few weeks. Upon his return there will be further proceedings.

General Gardiner and Solicitor Turner have returned to England, where they will report to their constituents. The principal ground of complaint on the part of the shareholders was that they had been led to expect dividends of from 70 to 80 per cent. They had only received dividends of from 1 to 1½ per cent. a month for ten months, and the dividend for the last two months of payment had been borrowed. They complain that on the strength of the promises of extraordinary dividends large sums of money were obtained from confiding shareholders.—*N. Y. Tribune, Dec. 30th.*

Mining Operations in Calaveras County.

The Calaveras *Chronicle* says: A review of the field of mining operations in this county develops a most encouraging condition of that interest. In both quartz and gravel mining the progress being made is wholly satisfactory, and the outlook for the future is as promising as could be desired. In the West Point, Mosquito, Railroad Flat and Sheep Ranch districts a greater number of ledges are being worked, more men and capital are employed and more bullion being produced than at any other time since the inception of quartz mining. Increased activity is also observable in other districts throughout the country, and we are constantly hearing of the inauguration of new enterprises. The success attendant upon the extended operations at the Gwin mine, located on the great mother lode of the country, has crystallized faith in the permanency and value of our quartz ledges, into certainty, and been the means of redoubting exertions in their development. The idea of a shaft being sunk a thousand feet upon a quartz ledge in Calaveras would have been sneered at a few years since, and yet ore is being mined at that depth in the Gwin, to day, and better than all that, the operation pays. By the prosecution of this great industry employment is furnished, directly and indirectly to a large number of hands, and a quickening impulse given to other branches of business. Leaving aside the principal fact that quartz mining in this county is now more remunerative than formerly, the next feature in importance is that the hap-hazard, unsystematic style of prosecuting it is giving place to a methodical well ordered manner of conducting operations. Quartz mining has ceased to be regarded as entirely speculative in character. Men engage in it the same as in other legitimate enterprises, with a full understanding that it can be made successful only by a careful observance of the ordinary rules of business life. A great deal of time and money has been spent in ascertaining that fact, but the lesson is well learned and its utility will be felt in the future. Quartz mining in this county is yet in its infancy, but it is an interest of sturdy growth and is rapidly developing into one of first importance.

Even greater progress is being made in gravel than in quartz mining. In this vicinity, especially, that interest has revived wonderfully during the past two years, and we believe there are more sluice-boxes set now than at any time since water was first brought to Mokelumne hill. The reduction in the price of water, the introduction of labor-saving appliances and the knowledge gained by practical experience have combined in vastly enlarging the scope of gravel mining and increasing the product of it. Claims long since pronounced exhausted and abandoned, as well as acres upon acres of ground that the superficial prospecting of early days failed to develop the richness of, are now being energetically and profitably worked. The substitution of gunpowder and hydraulic pressure for muscle in the wearing away of our gravel banks has wrought a revolution in the whole system of mining—a change that is telling every day in the unparalleled development of that interest. And yet the reinvigoration of gravel mining has but just commenced. There are square miles of gold-bearing gravel fields in this county that the hand of the miner has not yet touched—repositories of wealth that the key of enterprise can readily unlock. The future of gravel mining in this county, judging from the rapidly increasing importance of that industry, is indeed promising and encouraging. But one county in the State—Nevada—now exceeds Calaveras in the production of its gravel mines, and the day is not far distant when even that solitary exception will not have to be made.

No other section of the State offers so favorable opportunities for the investment of capital in mining enterprises as Calaveras. This county contains a very large area of mining territory, and in consequence development has been slower than in sections where the mineral belt is confined to narrower limits. The county is now just thoroughly prospected, a fact that enables men of means to step in and make investments, based upon certainties which labor alone is powerless to take advantage of. Mines known to be valuable can be purchased cheap because the owners have exhausted their means in proving the worth of their property and will be forced to relinquish the prize when it is almost within their grasp. Capital is master of the situation, and can make investments upon its own terms. The field is certainly a most inviting one, and it will be surprising if men with money to put into mining enterprises do not make Calaveras the theatre of their ventures in the future.

The new hall of the miners of Ruby Hill was dedicated on the 30th ult.

Quicksilver Production of Colusa County.

The quicksilver production of Colusa county is rapidly rising into importance. Lying in a south west direction, and about thirty-five miles distant from the town of Colusa are a number of quicksilver mines in various stages of development; a few of them are sufficiently developed to prove them to be very valuable, whilst others, though but little prospected, show satisfactory indications of their future value. These mines are situated on Sulphur creek, and in the hills bounding Bear valley on the west. The Buckeye mine ranks first in the amount of quicksilver produced. This mine has been worked by the present owners for about three years. It has yielded during the last twelve months 520 flasks of quicksilver. The mine was worked with ordinary retorts until about two months ago, when the company completed one of Knox & Osborn's patent furnaces at a cost of \$11,000. The furnace is now running on quicksilver at the rate of eighty flasks a month, and the production will soon be increased to at least one hundred flasks a month. The Abbott mine is another well known and valuable mine. It has yielded a good deal of quicksilver during the last five years though until recently it has not been worked with regularity or system. Since the present company took charge of the mine, about eight months ago, it has been thoroughly opened, and a large amount of fine ore taken out. A furnace, similar in all respects to that of the Buckeye, has been erected upon the mine, and has been in successful operation for two or three months. The Abbott had no reduction works upon it before the completion of its furnace, but its furnace has already yielded 125 flasks of quicksilver, and is now producing about like the Buckeye, with equally fair prospects for the future. The Elgin mine, with one small retort upon it, has produced, within the last five months, sixty flasks of quicksilver. The mine is being constantly worked now, and is very promising. The Manzanita mine has no reduction works.

It has, however, been worked for several years, and considerable quantities of very fine ore have been taken from it and reduced elsewhere. During the last twelve months it has produced considerable quicksilver, but we are not informed as to the number of flasks. So with four or five other mines in the immediate vicinity. Good ores have been taken from them in large or small quantities, and they have all produced some quicksilver, but we are not advised as to the quantity. On the Bear Valley range the Turner mine is conspicuous. A furnace has been erected upon this mine and is now about ready to receive ore. A large quantity of good ore has been taken out and is now awaiting reduction. The mine, we are told, is very promising. We thus have for the year's production of quicksilver in Colusa county, 705 flasks as the total amount. We may probably add to this amount 45 flasks as the production of the several other mines above mentioned, which are not credited with the specific quantity of quicksilver taken from each during the year—making, in all, 750 flasks as the total production for the year. This is certainly a showing for a mining district that was unknown outside of the immediate vicinity six months ago, and for a mining district that is as yet almost wholly unprospected. Our quicksilver mines are beginning now to attract considerable attention, and they will probably present a very different appearance twelve months hence. Intelligent gentlemen, well acquainted with cinnabar ores, have lately visited our mines, and have expressed the opinion that we have one of the richest quicksilver regions in the State. It certainly presents a fine field for enterprising men and capitalists.—*Colusa Sun.*

The new 60-stamp mill of the Virginia Consolidated Mining company was started up on Thursday evening for a trial of the machinery. Another mill of the same size will be commenced for the California mine. The Ophir company will also follow suit with a big mill, and next the Sierra Nevada with a 60-stamper.

ENCOURAGING.—It may be an encouraging fact to some one to know that Ezra Corvel, the late philanthropist millionaire, was so poor at one period of his life that the lucky finding of a (New York) shilling in the street once prevented his going dinnerless.

TALL and bulky people require more sleep than thin people. In a state of health, the amount of sleep required to restore nervous energy averages from six to eight hours. Sleep on the right side, and eat nothing heavy before retiring.

JAS. TYLER, of Tyler's ranch, about midway between Lakeport and Cloverdale, has discovered a well-defined ledge of gold-bearing quartz on the ridge that divides the waters of Russian river and Clear lake.

The mining excitement at Varyville continues at fever heat; several new ledges have been discovered and located within the past week, and the hills are full of hardy miners hunting for more.

DURING the month of December 3,143 carloads of ore, aggregating 23,000 tons were shipped over the railroad from the Comstock mines.

THE Helena (Montana) *Independent* claims that the mines of Montana now produce a much larger percentage of precious metals per capita than any other mining region in the world.

[Business Notice.]

Mining and Scientific Press,

A VALUABLE WEEKLY FOR

Miners, Mechanics and Manufacturers on the Pacific Coast.

Volume XXX of this first-class, standard journal commences with the year 1875. Its proprietors, having the successful experience of ten years publication of the PRESS, have no hesitation in saying that for the ensuing year the paper shall, in keeping with the times, reach a higher mark of merit than ever before.

With our own printing press, folding machine,

Able Editors, Correspondents,

And skilled workmen in different departments of our now extensive and growing establishment, we mean to print a journal throughout the year, which all citizens, whether strollers or not, may be proud of seeing published and supported on this side of the continent.

No kindred journal in America furnishes more real

Fresh, Novel, Interesting Information

In its volumes than the MINING AND SCIENTIFIC PRESS. We have the

Largest Mining Field in the World

To report from. It embraces the largest variety of mines and mining; methods of working; and excommensurate wonderful discoveries than any other section of the globe. It is the birth place of many of the

Latest and Best Inventions in Gold, Silver and Labor Saving,

With brief, reliable, well chosen and prepared editorials; varied and condensed correspondence and selections; tables and statistics arranged for ready reference,

Superior Illustrations,

Of local and general interest to its readers, it forms a weekly journal of individual character and unrivalled worth to its intelligent and industrial Patrons at home and abroad. It is the

Leading Mining Journal of America,

And in its practical, interesting and substantial make up, it is unrivalled by any mining or mechanical journal in the world.

Home Manufactures and Home Inventions

Will be constantly encouraged. Both help to build up the brain and material wealth of the country. They are kindred to our individual enterprise. Our interests are mutual with all home artisans and producers. Where on the face of the globe do INVENTORS and MANUFACTURERS either NEED or DESERVE more encouragement?

Its Value to the Community,

In disseminating important information; dissipating false notions; checking expensive follies; instigating important enterprises; by wise counsel and scientific direction, enriching the rewards of honest labor, we are annually saving and adding

Millions of Dollars

To the products of our country. The PRESS has already

A Large Circulation,

And is deserving of more universal patronage from those whose interests it specially represents. This sparsely populated portion of the Union is a difficult one for publishers to present the claim of their journal in to all who should subscribe. In these times of seemingly cheap (but largely, trashy and worthless) journalism, it is desirable and proper that those who know the real merits of a faithful journal should

Speak and Act in its Favor.

We shall not spare our efforts to make sound and improved issues, maintaining constantly the rights of all, and forwarding the material and intellectual rights of our patrons, and of our sturdy, progressive community.

Necessarily, scientific and mining publications generally are costly and high priced, but considering the size, character and location of our publication, our rates are favorable for so valuable a print.

We invite correspondence from all sections. Subscriptions, payable in advance, \$4 a year. Single copies, postpaid, 10 cents.

ARE YOU GOING TO PAINT?

THEN USE THE BEST.

THE AVERILL CHEMICAL PAINT

WILL LAST THREE TIMES AS LONG as the best lead and oil, without CHALKING; is of any desired color. It is prepared for immediate application, requiring no Oil, Thinner or Drier, and does not spoil by standing any length of time. It is equally as good for inside as outside work; over old work as well as new; in fact, where any paint can be used the AVERILL CHEMICAL PAINT will be found superior to any other. Any one can apply it who can use a brush, which truly makes it the FARMER'S FRIEND.

IT IS JUST THE PAINT FOR THE AGE.

IT IS SOLD BY THE GALLON ONLY.

One gallon covers 20 square yards 2 coats.

For further information send for sample card and price list.

7-25-7f JOHN TAYLOR & CO.

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merit. They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:

The pan being filled, the motion of the muller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Sellers made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill-men are invited to examine these pans and settlers for themselves, at the office, 229 Fremont Street, San Francisco.

Grain Elevators.

For shipping grain in bulk on this coast, whereby an immense sum can be saved to our producers, we need elevators to handle the grain from cars and schooners to ocean ships. Consequently, we are happy to notice that Mr. Chase, of Illinois, is now at the Cosmopolitan hotel, in this city, with plans to show what can be done in this line to cheapen our wheat transportation. The *El Paso Journal*, Ill., give the following concerning the success of his elevators elsewhere:

The new system of grain elevation, by Henry I. Chase & Co., of Peoria, to which we have often called attention in these columns, is a great success; so much so that it promises to drive the other elevators out of the market. A new house of 600,000 bushels capacity is now going up in Chicago. The parties in Kansas City, Mo., who have just finished theirs, speak in high terms of it, and wherever it has been introduced it gives the most perfect satisfaction. Its main points are: First—Economy. It costs about half an old-style elevator. Second—Simplicity. It contains little machinery, and can be run with one quarter of the force. Third—Safety. It is built on the ground, so that neither the tornadoes of the prairies nor the earthquakes of the mountains can shake it. We have seen a great many parties who have witnessed its workings, and we never saw any one yet who was not perfectly satisfied with it in every particular. Cheap, strong, simple, durable; it is destined to revolutionize the present system of grain handling in the West.

General News Items.

THE BLACK HILLS.—The avaricious gold-seekers who had defiantly pushed their way into the Black Hills country in spite of the warnings and prohibitions of the Government have been driven out by the cavalry under Capt. Henry. This is a disagreeable climate in the winter—an Iceland compared with the gold and silver fields of California. Let the expelled miners turn their steps to California, and they will find richer mining than will ever be developed east of the Rocky Mountains, in a climate unequalled even in sunny Italy, with abundance of game to satisfy all their sporting desires, together with the more substantial food and necessities of life while mining. We may remark in this connection that recent disclosures at Washington, seem to indicate that the gold reports from the Black Hills have been an artifice in favor of a country through which interested parties desire to build the Northern Pacific Railroad.

THE BREBEY INVESTIGATION.—The committee having this matter in hand have traced \$750,000 to the very doors of Congress, where it disappears in the hands of men who refuse to tell what became of it. Under these circumstances it is impossible to avoid the conclusion that some of it found its way into the pockets of members; and this conclusion brings into suspicion every member who labored or voted for the subsidy. The great mass of members cannot afford to rest under such suspicion. They must insist upon a full disclosure from those into whose hands the money has been traced, whatever the consequences may be. The order of the speaker confining Irwin to the common jail, and indicating the commencement of legal proceedings which will continue his confinement after the expiration of Congress, is a step which does no good to any one either directly or indirectly connected with this disgraceful transaction.

THE NEW CURRENCY BILL.—The bill for the resumption of specie payment which has just passed both Houses of Congress, provides:

First—A redemption of legal tenders, and of resumption of specie payments four years hence, on the 1st of January, 1879.

Second—Free banking, in the widest sense of an unlimited issue of National Bank currency.

Third—A withdrawal of 80 per cent. of the amount issued in new bank currency from the volume of greenbacks, until the amount of \$300,000,000 for United States notes is reached.

Fourth—A substitution of small silver coin for fractional currency.

Fifth—An abolition of the mint charge.

KILLED BY A FIELD ROLLER.—A severe and perhaps fatal accident occurred to Mr. Campea, of Borden, on the 4th inst. He was engaged in rolling his land, and some part of the wood-work of the rolling machine on which he was riding gave way, and he was precipitated to the earth in front of the roller, which passed over his body, crushing and mangle him in a fearful manner. The roller weighed 1,500 pounds.

THE FIRST DETENTION.—The first severe storm and cold weather during the winter occurred on Saturday night along the Union Pacific railroad. The thermometer marked 16 degrees below zero at Omaha, and 26 below at Cheyenne. The westward bound Union Pacific train was eleven hours late at Green River on Saturday evening.

COMING TO AMERICA.—It is said that Emilio Castellar, the eminent statesman and Republican leader of Spain is coming to this country. He will meet with a warm reception here. Spain, under its present regime can have but little attraction for him—even if he could remain there with safety to his person.

RECIPROCITY WITH HAWAII.—Dispatches from Washington say that if the negotiators act promptly in settling up the details of the Hawaiian reciprocity treaty upon such a general character as is understood to be contemplated, there is no doubt of its prompt ratification by the Senate.

SCOTT'S RAILROAD BILL.—Efforts are being made in Congress to have Tom Scott's bill amended so as to connect the Texas Pacific railroad with the Central Pacific railroad at Fort Yums, and thus leave the latter undisputed control of the great route with California.

ACCIDENTS AT THE PALACE HOTEL.—Several accidents occurred to workmen by falling from beams and scaffolding at the Palace hotel during the past week. One of the natural results of building too high.

THE HEALDSBURG FLAG. states that a fire occurred in Point Arena Thursday last, which destroyed Lyman's hotel, McMullen's saloon, Shoemaker's saloon, and a house belonging to Iverson.

RAILROAD FARES IN NEVADA.—A bill has been introduced in the Nevada Legislature for regulating railroad fares and freight tariff in that State. A lively discussion may be expected.

BANK NOTES BURNED.—Nearly \$400,000 in new National bank notes were destroyed by the burning of a postal car on Thursday of last week on the Potomac railroad.

THE BIG BEAR THAT KILLED BERRY near Sierra valley a few weeks since was dispatched last Thursday by a party of hunters. Bruin weighed 800 pounds.

THREE MEN WERE BURNED TO DEATH by the destruction by fire of the Western Hotel at Sacramento on Saturday last.

Agricultural Items.

ANGORA GOATS.—The Watsonville *Pajaronian* learns that E. R. Marsh, of San Francisco, has recently invested \$27,000 in Angora goats; also, Wm. Hall, of San José, lately purchased a lot at \$11,480; and C. S. Abbott, Flint, Bixby & Co., and B. Boswell have bought up all the stock of the Guadalupe Island company, except about 300 shares, and the stock held by Landrum & Rodgers. These men represent several million dollars, and mean business in goat raising. We may note in this connection that Landrum & Rodgers, of Watsonville, will, during the next two months, ship about 3,000 pounds of mohair to Philadelphia.

THE SANTA CLARA VALLEY AGRICULTURAL ASSOCIATION on Thursday elected the following officers for 1875: President, W. C. Wilson; Vice-Presidents, Cyrus Jones and Jessie D. Carr; Secretary, Givens George; Treasurer, C. T. Ryland; Directors, William O'Donnell and S. J. Jamison.

In the foothills of Fresno county grass and volunteer grain is so forward that it would now make good hay. A gentleman informs the *Expositor* that he cut hay on his ranch on the last day of the year, but he couldn't cure it for the want of sun.

THE LAKEPORT BEE is informed that the tobacco crop planted near Guenoc last year by A. A. Ritchie has proved successful. The crop has been cut and saved, and will be cured the coming spring.

In the vicinity of Santa Barbara, a farmer last year raised over 60,000 pounds of Florida tobacco on 30 acres of land. He has sold the same at 40 cents per pound for Eastern shipment.

It is reported that in Yuba county the cherry buds are much swollen, and that the frost has nipped a good portion of the crop.

The next annual fair of the Santa Clara Valley Agricultural Society will be held the week following the close of the State Fair.

The continued dry weather has seriously injured the volunteer potatoes growing near School House station.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington, D. C., Jan. 12th, 1875.

FOR WEEK ENDING DEC. 29th, 1874.

ALMOND GRATER.—Julius Leroy, S. F., Cal.
FRUIT DRIER.—William S. Plummer, S. F., Cal.

HAY PRESS.—John Wiley, San Andrea, Cal.

The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest time possible.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses menagerie Seal Ponds, and Skating Rink.

Industrial Items.

MANUFACTORIES AT THE SOUTH.—It is said that the cotton factories recently established at the South are the best paying industrial institutions in the country. They have proved that the fabric could be worked to more pecuniary benefit where it was grown than in those portions of the country generally known as the manufacturing districts. An important point, this, for California capitalists.

BOSTON ENTERPRISE.—Boston is showing much enterprise in further pushing out her iron arms for the trade of the West. A special committee of the Massachusetts Legislature is now examining the terminal facilities of the Baltimore and Ohio Railroad company, for the purpose of legislative action in making South Boston flats the terminus of a through railroad line from the West to that seaboard.

TUNNELING THE NIAGARA.—A plan for tunneling the Niagara river at Buffalo has been prepared by William Wallace, an engineer of that city, who estimates the cost at about \$1,500,000.

SHIP BUILDING at Vallejo is proving a great success. A fine schooner was launched on Saturday last for which \$32,000 has already been offered.

The Palace hotel will formally open about the 1st of September next. A hundred miles of telegraph wire are in use to connect the rooms with the office.

A JOINT stock company has constructed skating rink at Winnemucca. Perhaps, however, this may not be considered an industrial item.

SURVEYORS are at work on the survey of the proposed narrow gauge railroad from Pescadero to Pigeon Point.

The Sacramento angarie has just erected a large two-story building for a distillery and potash factory.

The proprietors of the Marysville Foundry will soon establish a branch establishment at Chico.

The California Chemical Paint company has increased its stock from \$150,000 to \$2,000,000.

A box factory has been started at Nevada City.

TEMPTING DEATH.—Every man or woman afflicted with a cough or cold, which he or she takes no measures to arrest, is tempting death. There is no drug store in the land where *Hale's Honey of Horchound and Tar* may not be procured, and there is no ailment of the lungs or throat tending to consumption or bronchitis, which it is not competent to cure. Do not suffer cold to accumulate on cold, but arrest the first symptoms of pulmonary disease, and tone and invigorate the breathing organs with this wonderful remedy. *Pike's Tooth-Ache Drops*—Cure in one minute.

Mining Machinery.

THE
AMERICAN TURBINE WATER WHEEL

Recently improved and submitted to thorough scientific tests by James Emerson, showing the following useful effect of the power of the water utilized, being

THE HIGHEST RESULTS EVER KNOWN.

Percentage of part gate, $\frac{1}{2}$ 50.08; $\frac{3}{4}$ 69.64; $\frac{5}{8}$ 78.73
 $\frac{1}{4}$ 82.53; $\frac{1}{2}$ 82.90. Percentage of whole gate, 83.14.

Mr. Emerson says: "These are the best average results ever given by any Turbine Wheel in my experience."

A splendidly illustrated descriptive catalogue, or any further information desired, furnished on application to

TEATS' PATENT FURNACE.

TEATS' PATENT FURNACE

For Roasting, Desulphurizing, Chloridizing and Oxidizing Ores, etc. For the reduction of Gold, Silver, Lead and other ores, saving a larger percentage, at less cost, than any other invention now in use. Chloridizing Silver ore more thoroughly, in less time, with less fuel, salt and labor; also roasting Lead ore preparatory to smelting, better and cheaper than any other invention. The Furnace is so constructed that one man, of ordinary ability, tends five or more furnaces; controls them with ease; adding heat or air; stopping or starting at will; charging and discharging with ease. Also, Patent "Conveying Cooler," for conveying and cooling roasted ores, heating the water for amalgamation and the boilers at the same time. Saving the large space in mill (covered with brick or iron), and the labor of two men per day, exposed to the poisonous chlorine gases. Also, Patent Air Blast "Dry Kiln," for drying ore direct from the mine of breaker, saving fuel and labor heretofore necessary in drying ore for dry pulverizing. For description refer to MINING AND SCIENTIFIC PRESS, No. 13, October 31, 1874. For particulars address

TEATS & BREED,

No. 12 West Eighth Street, Cincinnati, Ohio
Circulars, &c., will be furnished, if required.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

[PATENTED MAY 26TH, 1874.]

Price Reduced to 16 Cents Per Pound.

SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally:

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburgh Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES and DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent. cheaper than the best iron. There are no STEEL SHOES and DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES and DIES which are only cast iron hardened by the addition of a composition. They will not outwear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, dying from under the hammer like cast iron. Our STEEL SHOES and DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 50 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to

TREADWELL & CO.'S
(IMPROVED)
Upright Safety Engines and Boilers.
(MADE BY THE NEW YORK SAFETY STEAM POWER COMPANY.)

We would call particular attention to the graceful design and simple mechanism of this Engine Boiler, the form in not only pleasing to the eye, but is also, that which secures the greatest efficiency and safety in its operation. The material of the Boilers, which are of the best Tubular style, with internal are box, are of the best material and workmanship, and are all tested to 150 pounds per inch. The heating surface and area of grate are in excess of the quantities usually allowed for the same power, and it is therefore unnecessary to purchase a greater rated power than is actually required, while in cases of emergency these boilers are capable of being increased in power by the addition of the Engine is not fastened to or upon the boiler, and is therefore not affected by expansion, nor are the bearings over heated by conduction, or the heat from the boiler. The fly wheel being at the base secures perfect steadiness under the high speed which is necessary for economy of fuel. All parts are easily accessible—a great advantage. Its complete in itself as a Portable Engine and Boiler, or the Engine can be detached from the boiler, and used as a portable engine, if required. Its main points are simplicity, safety and economy. For printing offices, laundries, tanneries, ranches, small repair or machine shops, or for hoisting, wherever a small and safe power is required, they are peculiarly adapted. Over 500 are already in use.

Engines
Sole Agents
TREADWELL & CO

The above cuts represent the new style "HOADLEY" variable cut-off 15 Horse-Power Portable Engine. We have same style and size mounted on wheels as a Threshing Engine for the Russell End-shake Separator. We have all sizes from 3 to 40 horse-power on hand. The HOADLEY ENGINES need no recommendation from us. We have sold them in California for 20 years, and every year has added to their improvements. The last great improvement is the Cut-off Governor, thus giving them all the economy and increased power of the most thorough built stationary engine. Millmen, Mine-owners and Mining Superintendents, and all who intend buying engines, will do well to examine carefully the merits of the "HOADLEY" before purchasing. Circulars and prices sent free on application. Address

Number 4.

Improved Pinking Iron.

This is an ingenious and handy substitute for the old-fashioned siaking iron, or one under which the cloth is usually laid and the cutting done by pounding on the end of the tool with a hammer.

The present invention is nothing more than two cutting blades, of any desired form, attached to levers which are jointed like pincers and are operated like scissors. The upper blade does the cutting, and the lower one is made to correspond to it in shape, having its edge made, however, by beveling one side only. Both are so constructed that, when the jaws are closed, the edge of the upper blade sinks slightly below the surface of the lower tool and just back of the same, so that at each stroke the beveled parts of the blades bear against each other, and the cutting edge strikes against nothing but the fabric.

Of course the dice or blades are varied in form for different patterns, but it is considered cheaper to have an entirely separate instrument for every pattern instead of providing detachable blades.

For further particulars regarding sale of State rights, etc., address the inventor, Mrs. Eliza P. Welch, Groton, Caledonia county, Vt.

Some one might make a profitable investment, by purchasing the right to the Pacific Coast, of the above iron which evidently will be a very useful article.

Hydraulic Mining in California. No. 9.

The caved material is washed into the sluice boxes, good care being taken that an even flow is maintained and that the boxes are not over-charged. Pieces of hard gravel, clay, etc., too large to be washed through the sluice boxes, must be reduced to smaller fragments, by either the pick or the blast. For all such material as can be perforated by the churn-drill or angler, the process of blasting with giant powder No. 1 is considered the cheapest and most effective. Rocks and boulders, too large to be sent down by the sluice boxes, must be first broken up. It is to be presumed that as yet room is wanting to stack them in piles on the ground.

When efficient clearance has been made to leave ample space for the deposition of heavy boulders, tree stumps, and other rubbish, either a derrick, or wheelbarrow, or cars can be employed to remove such objects to the place of deposit. Even with abundance of room it will be advisable to go systematically to work and keep certain order in the arrangement. This plan will accustom workmen to dispose at once of any impediments for good and at the right place, and will save a great deal of work in the long run.

In working a hydraulic mine it must be the aim to secure as soon as possible a large open front, so as to occupy two, three, or more hydraulic nozzles, according to the supply of water and general capacity of the works.

These different hydraulic nozzles, being supplied from the same distributor, can open a "cross fire" upon any point within 200 feet from the nozzles and thus do excellent execution.

Should the surface of the gravel deposit be covered by a growth of brush-wood or trees it will be necessary to remove this material by cutting it down and hauling it off the ground, or piling it up and setting fire to it.

Bank Blasting.

This is resorted to either when the gravel de-

posit is so hard that it will not readily yield to the jet, or when the gravel bank is so high that the hydraulic nozzle cannot with safety, (on account of caving) be brought close enough to do good execution. The blasts may either be placed in drifts with one or more cross drifts, (T,) or in shafts with a cross-drift in the bottom, (L,) or in shafts with a wider bottom (in the shape of a bottle, the shaft forming the neck of the bottle.) The latter are generally used to blow up patches of bottom gravel. The quantity of powder used depends necessarily on the quality and extent of the ground to be blown up, and varies from a few kegs up to two thousand. Even larger blasts have been and will be made, as occasion requires. A keg of powder contains 25 pounds.

When a bank is from 80 to 100 feet high the main drift should be 100 feet long, so that a reasonable proportion may exist between the resistance offered by the top pressure and the lateral or front pressure. Thus a general upheaval results, and neither a blowing out of the front nor a partial blowing up of the top. The

from the mouth of the main drift, each arm being 30 feet long. We shall thus have the accompanying figure.

This blast fired by an electrical apparatus and ignited simultaneously at twelve or sixteen

WELCH'S PINKING IRON.

main drift should be three feet wide and four feet high, or as small as it can be worked. The side-drifts or "Ts" can be made a little larger.

Fig. 1. Nitro-Glycerine Igniter.

To secure a good effect, it is necessary to use about 600 kegs of powder for the blast, placing the contents of 400 kegs on the cross-drifts at the termini of the main drift, each arm being from 45 to 50 feet long, and the contents of 200 kegs in the cross-drifts, located about 65 feet

different points, will in all probability dislodge and crumble an area of ground, representing from fifty to sixty thousand cubic yards.

The powder should be emptied in long boxes placed in the different side-drifts, and electric fuses should be inserted, at proper distances, at least one for every 40 or 50 kegs of powder,

Fig. 2. Mixer for Acids and Glycerine.

which would insure the simultaneous ignition and complete combustion of the gunpowder and develop thus its whole force at once.

Condensed from an article by Charles Waldeyer, of the last Annual Report of the U. S. Commissioner on Mining Statistics.

For the year ending January 1, 1875, the Eureka mill, on the Carcon river, Wm. King, Superintendent, reduced 61,100 tons of ore, producing 80,347 pounds of bullion, worth \$3,435,131.53. The mill contains sixty stamps and the adequate amount of amalgamating machinery.

Nitro-Glycerine Compounds.

The invention of combining nitro-glycerine with other substances to furnishing a substitute for powder in blasting operations has been one of great benefit to the mining interests. The peculiar property which distinguishes this class of substances, is that fire may be applied to them without their exploding. Nitro-glycerine, if ignited in an open space is slowly decomposed with a bluish flame, but the fire goes out when the match is withdrawn. If a drop is placed on an anvil, the blow of a hammer, through the heat developed by compression causes it to explode, but only that part which has received the blow, so that the explosion in this case is only a local one.

A chief point in Noble's inventions consists in overcoming this difficulty, and he adopts two different methods of promoting its explosion. The method to be used in blasting, where evidence of explosion is of great importance, is that by which it is submitted to pressure, the most rapid source of developing heat. There are many means of attaining this impulse of explosion.

Some of these are as follows: when nitro-glycerine in tubes is surrounded by gunpowder and vice versa; by an electric current when the nitro-glycerine is enclosed on all sides, so as not to afford an escape to the gas developed by a capsule; by many chemical agents developing a gradual heat; simply by a fire; by igniters.

These igniters are shown in figure 1 of the cuts. They may be equally varied, but in their simplest form they consist of a wooden cylinder, hollow inside and filled with gunpowder, being corked at one end and connected with a fuse at the other. When the nitro-glycerine has been poured into the bore, this cylinder is let down with its fuse until the former swims in the blasting oil; then the upper part of the bore is filled with loose sand, and nothing remains but to ignite the fuse. The fuse in its turn fires the gunpowder contained in the wooden cylinder, the hot gases of the gunpowder make their escape and rush in streams into the blasting oil, of which they heat a minute part; a local detonation takes place, which as the oil cannot escape, heats it by pressure to about 360 degs., F. when it explodes through the whole blast. In the figure referred to, a, a, shows the work, b, b, the bore, c, c, the nitro-glycerine, d, d, the wooden cylinder (igniter), e, the charge of gunpowder, f, the cork, g, g, the fuse, and h, h, the shaft of loose sand.

Among other improvements of modes in the manufacture of this compound consists in rapidly mixing the whole relative quantities of acids and glycerine, which being led immediately into cold water the nitro-glycerine separates, being insoluble. The old way was by adding glycerine drop by drop to a mixture of sulphuric and nitric acid, and taking care not to raise the temperature above 32 degrees Fahr. In the method of making referred to above, where it is mixed in once, is shown in Fig. 2 of the engraving. In this a is a tube conducting the mixture of nitric and sulphuric acids into the mixing tube, c; b is a tube conducting glycerine into the mixing tube, c; c is a mixing tube wherein the re-action takes place, and is provided with small holes at the bottom, whence the mixture of acid and nitro-glycerine escapes into cold water.

THE MECHANICS' ART LECTURES.—We had prepared a summary of the lecture on the "Production of Silver Ore," delivered on Saturday evening by Prof. Becker, of the University of California, but are compelled to leave it over until next week for want of space.

New discoveries continue to be made in Peavine district, and some of the specimens sent to Virginia City give high assays. It is thought there will be considerable excitement in that vicinity next season.

THE Helena (Montana) Independent, says the miners up at Ten-mile quartz mines, in going to work, slide down that shaft on icicles. A nice slide.

CORRESPONDENCE.

Notings from Tybo, Nevada.

From the Old to the New.

EDITORS PRESS:—Old Fether Time has been instrumental in effecting a chronological change since my last letter reached the editorial seat of the Press. 1874, feeble and decrepit with age, has been borne to thosilent chambers where calmly repose the remains of its more notable and illustrious predecessors. Its course was unmarked by aught of a nature to effect the common current of our thoughts, or desert them from their everyday ploddings. If there have been no great national or physical revolutions to chronicle during its career, we have had that given to us which is infinitely better and worthier of our attention than either sanguinary wars or chaotic revolutions. A measure of prosperity has been vouchsafed to the people of this coast during its passage greater than they have ever before enjoyed.

Mining and agriculture have both flourished in a manner unprecedented in the annals of statistical production; nor have manufacturing and other interests been a whit less prosperous. The production of bullion has, as we know, largely exceeded that of any preceding year, and it is certain that the product of 1875 will be still larger. The great bonanza will soon begin to pour forth its long dormant treasures, to enrich and stimulate the commerce whose broad sails whiten the waters of the Occident, while heaving to its masts the rich products of the orient. These riches will effectually eclipse by their vastness the amounts which have been at various periods drawn from the most famous mines of either ancient or modern times. The fame heretofore so freely accorded to the Veta Madre of Central Mexico, and the San Luis Potasi, of Buenos Ayres, will not any longer be entitled to receive the homage of either our admiration or remembrance, when we come to recall the figures of Mr. Deidesheimer, which are almost beyond the capacity of ordinary arithmeticians, \$1,500,000,000 in bullion! No wonder that he thought people who saw these figures would be inclined to set him down as a crazy man, and a fit candidate for Stockton. So much for what the old year has done for the Great West; and it faded from sight, down the horizon of time. We will now turn to the affairs of the Great East.

And inquire what are its prospects for the year which has so auspiciously dawned upon it. From every camp within its borders comes the most cheering accounts. New mines are every day being developed, and old ones long idle, are being opened and worked anew, with a confidence which shows the abiding faith and enterprise of their owners. From

Eureka

There is waited to us news of a very inspiring character, and from its tenor there is every reason to believe that the great bonanza will not be allowed to quietly beer off with it all the honors to which it now aspires. The vast mineral resources of Ruby Hill are not yet exhausted. Nature has lavished her treasures with no sparing hand upon that favored locality, and the bullion returns of the three companies whose properties cover its surface area leaves ample evidence to this fact. Not one of these three companies have since their incorporation levied an assessment, and two of them, the Eureka Consolidated and the K K, have paid in hard cash to their stockholders dividends aggregating \$750,000—the former, \$700,000, the latter, \$50,000. The affairs of the last named are, however, but indifferently managed in San Francisco, otherwise its shareholders would have been able to pocket more substantial rewards. Such will continue to be the case, too, so long as self-interests and the narrow policy which they invariably produce are considered paramount to the public good. Messrs. Heggins & Tevis have never been accused of much liberality toward parties with whom they have been associated in mining. These two gentlemen at one time in its early history controlled and directed the destinies of the first named company, and the result of their administrations are well known. They also control the financial affairs of the K K to such an extent that those who know and appreciate the mine best, even though seeking cheap and profitable investments, will not touch its stock so long as they have anything to do with it. This apathy of the public is evidenced by the fact of its being hardly ever called on change nowadays. The third of these companies,

The Richmond,

Which, though stocked in London, where such things are differently managed still maintains its prestige in that great mart, being by last advices, quoted at \$36, and paying the regular dividend of 27 and 30 per cent. to its lucky share-

holders. These dates, too, could have been mysteriously increased were its concerns here only skillfully managed. But they are not, as the sequel would show, were I, at present, at all desirous of undertaking the task of pointing out wherein things are, and have been of late, mismanaged. The Richmond is, however, a great mine, and worthy of the high encomiums that are lavished upon it. The amount a bullion it produced from the 1st of September, 1873, to the ending of the financial year, 31st August, 1874, has been \$1,775,000. Out of this large sum, there were \$375,000 paid for charcoal alone, to the people of the Base Range; this, and the other expenses leaving a net revenue of \$455,000. A large proportion of these expenses have, however, been debited to construction account, for the extensive refining works which are in process of erection and nearly finished, will absorb no inconsiderable sum. The entire cost will be about \$80,000. But whether they will ever be of any greater benefit to the company than the amount of oxide of lead which they will give, for smelting purposes, is a question which has yet to be solved. Experience is a stern teacher, and experience will, without I am mistaken, prove how fallacious have been the hopes of its projector, whose pet scheme it has been all along. No matter, it gives evidence of enterprise and enlarged views, and will prove ornamental if not either useful or profitable.

The mine is in a very prosperous condition, the late strike being the richest and most important, as regards size, which has ever been made in eastern Nevada. The Richmond is in the full zenith of its glory and productiveness, and there is every probability that it will long continue so, too.

The other mines of Eureka are also doing well, and give much future promise, and I would gladly particularize them had I time and space in which to do it. It is, however, enough to say that the prospects are as good, if not better, than they have been within the memory of the writer. From

White Pine

District, distant 45 miles from Eureka, and 80 miles from Tybo, in a northeasterly course, there comes many flattering reports. This place was, at one time, the Mecca of the hopes and aspirations of the thousands, who, like the writer, bent their steps toward it in 1868 and in 1869. But, however ardent we were at the outset, neither the pilgrimage thither, nor the experience gained there, proved to be quite as consoling in their effects as those which the devout Mussulman desires from a visit to the resting place of the prophet. It is not, however, at present, devoid of interest; nor will it be, provided Capt. Drake is but as successful in the future as he has been in the past. His management of the Eberhardt and Aurora company's property during the past four years has been marked by sense, judgment, and ability of no mean order. These mines have produced in that period, a sum equal to \$1,835,000, yet the company was at one time brought to the verge of bankruptcy, by the neglect and inefficiency of its then manager, whom it is needless to name. Mr. Edward Applegarth was the vendor of this now magnificent property to an English company, and he is now one of its directors. The company is now out of debt, and extracting 50 tons of ore a day, valued at sixty dollars (\$60) per ton, and at a recent meeting debentures to the amount of fifty thousand dollars (\$50,000) were subscribed for by its members, in order to inaugurate the new year's start with full coffers. The news from Cherry Creek, Pioche, Patterson, Robinson, Pharamagot, and other places to the east and south of here, is of the most cheerful character, thus showing that the prospects for 1875 are bright and encouraging.

To come to localities nearer home, I will mention

Rattlesnake Canon,

Hot Creek district, as the first of them which I will notice, because of its greatest proximity to Tybo, being only seven miles to the northward. Some of the leading mines of this camp are owned by a New York company, whose supineness of late has been a matter of comment. It has, however, not long since again commenced active operations, with a view to push developments ahead. Much headway cannot, however, be made until hoisting and pumping machinery are supplied, and I am informed that these have been already ordered from New York. Several of the claims, which were for a length of time lying idle, were re-located on the 1st instant, by parties who mean business. I have myself received from there within the past week three samples of milling ore for assay, which I am confident, as are those who have seen them, will go away up into the hundreds, and possibly into the thousands. The

Hot Creek

District contains many distinctive features of curiosity and interest. It receives its name from a rather singular stream of hot water which flows from several boiling springs in the neighborhood, which forms a stream of considerable proportions. It takes its course through a chasm in the mountains the walls of which rise vertically several hundred feet on each side, and flows a distance of a couple of miles and disappears suddenly through the sands and alkali beds, the same as does all other streams of Nevada. The old.

Milk Spring

District is situated in the Hot Creek range 45 miles east of Belmont and twelve miles south of this camp, close to the line of the projected Palisade and Colorado railroad. Its geologi-

cal formation is of limestone, in which occurs the silver-bearing veins, whose course is north-west and southeast, and dipping, like here, to the east at an angle of 60 deg.

Comparatively little has been done toward the development of its mines, yet they have been sufficiently opened to prove them true fissure veins. The district is, however, about to be re-baptized in consequence of some new and important discoveries which lately have been made there. Whenever this interesting ceremony shall occur, I shall communicate the facts to the Press, together with the mining laws and such other data as will prove of interest to its readers. From

Belmont

We have the intelligence that work is being pushed ahead on the 300-foot level of the Belmont mine as rapidly as possible. The connection with the winze in which the new body of ore is known to have been out, will be effected early this month. When once made stoping will be commenced and the mill once more started upon this ore. Orders have been received from San Francisco to put a force of men to work on the Central Belmont mine at once. The El Dorado South Consolidated company is out with notices for bids for sinking a perpendicular shaft 100 feet—6x16 on its ledge. The Josephine and other mines are about to be started up immediately, so that the folks of our sister town may soon look for lively times.

Jefferson Canon,

Too, forty-seven miles from here, is turning out to be a place of considerable importance. The Prussian North and South mines are yielding very rich ores, and in quantities to keep the two ten-stamp mills in full blast. Their product is about \$3,000 per diem in bullion, which is shipped to the Belmont bank, and, there is in addition, a great deal of prospecting going on in every quarter of the district. The population is about 400, and the above two mines and mills employ about 150 men. The mines are rich and the future radiant, and what more does Jefferson need?

Springfield District.

This is a new district, situated on the west side of Monitor valley in this county, and about 30 miles from its seat—Belmont. The Sheba ledge is among its most important discoveries. It is from 10 to 12 feet thick, and its outcrop has been traced a distance of 5,000 feet. It is opened by shaft and tunnel, the former 80 and the latter 100 feet, along the course of the foot-wall. The ore is base, and contains in itself sufficient flux for its treatment in a cupola furnace. Experts (?) who have examined this mine, claim for it in thickness and general average, a superiority over the famous Two G mine of this place, the property of the Tybo Consolidated company. These things may be so, but whether they are or not, matters but little. Our mental equilibrium is not disturbed by the thought; nor is the importance of the Two G any the less diminished if such is the case. We are not at all envious of the Sheba, but on the contrary are delighted to have it in our power to be able to give it this gratuitous notice, and to pronounce it a worthy property into the bargain.

Having in the foregoing paragraphs given a general glance at the prospects of the west and east sections of the State for 1875, and pointed out some of the distinctive features of interest in connection with the circumjacent camps, we will now see what progress has been made in the development of the mines of Tybo, since the 4th ultimo, the date of our last article to the Press.

The Tybo Consolidated

Company's property—particularly the Two G—has been steadily and successfully worked since last writing. The vein was at that time opened to a depth of 298 feet; it is now penetrated to a depth of 323 feet, and exhibits at this point ore of a remarkably fine grade. The assay value of the two classes of ore found at this depth, is—galena, \$331—and quartz, \$56—or an average of \$198.50 per ton, thus proving the increased richness of the vein as depth is attained. The lode is now developed longitudinally 560 feet, by tunnels or adit levels one and two, which are still being driven ahead. It has, however, increased in thickness toward the deep, being now five feet in the clear between walls, and preserves with the utmost exactitude its angle of inclination. The milling and smelting ores, also, continue their course, side by side, but have reversed situations, the former now showing its affinity for the silicious lime hanging-wall, and the latter for the foot or porphyry wall. This is proper, and in accordance with the laws of gravitation.

The outlook is all that could be desired, there being now exposed in this mine alone, in the neighborhood of 60,000 tons of ore, ready for extraction and reduction. This amount would more than suffice to keep a 20-stamp mill and a 50 ton furnace in full blast for a space of two years. Explorations will, however, be pushed ahead vigorously, in order to still further test the value and productiveness of the mine.

The Lafayette

Has also been worked with success, since last notice of it, a large quantity of \$150 ore having been mined and worked. This mine, an offshoot from the mother, or Two G vein, exhibits all of its mineral and structural attributes. Active operations have also been commenced on the

Crosby

Mine, located on the extreme northwest of the lode. A new shaft is being sunk on it, through

ore of the same quality as found in the two former.

The Casket

Is at present idle, and will be until hoisting works are supplied sometime during the coming summer. This mine is opened by two shafts, which cut the vein at a depth of 65 feet each. A new shaft will, however, have to be sunk at the point of divergence of the Lsytayette from the main lode, over which the hoisting machinery is to be permanently placed, for the working of both. A new shaft through which to work the Two Grand Casket mines, has been sunk a distance of 60 feet, but had to be abandoned for the want of suitable lumber with which to line its compartments, when this is to be had, work will again be resumed upon it.

The Furnace

Shut down for much needed repairs on the 29th ultimo, having made a run of exactly 30 days, which, added to the 59 days formerly mentioned, makes 89 days altogether that it has been engaged in the production of bullion. It reduced in the last 30 days of its run 700 tons of ore which produced in the aggregate 80 tons of base bullion, valued at \$36,000, or \$4.50 per ton in gold, silver and lead. This showing is a good one and is far ahead of the last one given in the Press. Up to that time the furnace ran on the whole 59 days, reducing 1,260 tons of ore, which produced 153 tons of bullion, valued at \$62,000. Adding these two together we have a total of 89 days run, in which there were reduced 1,960 tons of ore, which yielded 233 tons of crude bullion valued at \$98,000. This is not an unfavorable showing, all things considered. With increased working facilities, this exhibit will be largely increased. With a 20-stamp mill and a couple of furnaces in full blast, as there will be next summer, we may look for prosperous times in Tybo. There are already 90 tons of the mill material to haul, and the balance is expected at an early day, so that this structure will soon add to our prosperity. J. D. P.

Tybo, Nevada, Jan. 12, 1875.

Esmeralda.

EDITORS PRESS:—It has been many years since I have seen anything in your columns relating to the once important Esmeralda mining district; and in truth there has not very much transpired in the district worth recording, although that it still possesses much importance as a "mining camp," I, in common with many others, still firmly believe.

During the great stock fever of 1862, '63 and '64, the credulous and then comparatively inexperienced people of California were most wretchedly humbugged and swindled by having wild cats of all kinds, sizes and colors palmed off upon them as genuine mines by unscrupulous stock sharps and swindlers. The result was that the reputation of "the camp" suffered by having odium cast upon the good mines as well as poor ones—or none at all. Stockholders refused to pay assessments for the purpose of prospecting the mines to any depth, and when the rich boulders, found on the surface, and the richer "bonanzas" which were found in the veins near the surface were worked out, the work stopped, and mills which cost from \$125,000 to \$250,000 have been idle from that day to this. And the fact is, the lowest depth attained in any of the works is, I think, not over 200 feet vertically.

In 1867, John D. Winters, who had a mill here, made an effort to sink deeper and prospect thoroughly the Juniata mine, located one mile easterly from this town, but he having become bankrupt by business complications elsewhere the work was stopped, while everything in and about the mine looked extremely encouraging.

Matters have remained substantially in statu quo until about three months since, when the Juniata Consolidated mining company, which owns the Juniata proper and also the once famous real Del Monte, Wide West, Pond, Ural and other lodes, started in the old works with vim and energy, under the skillful superintendence of Mr. Warren Rose. Much time has necessarily been lost in cleaning out the old shaft and drifts, as a new steam pump had to be procured, roads made, etc. But now they have arrived at a point when their work will soon tell, and all the citizens—many of whom have stood by the place through prosperity and adversity since 1860 and '61—confidently predict that in due course of time developments and discoveries will be made, which will not only richly remunerate those immediately connected with the enterprise, but will also lead to many like operations in the district. Many being of the opinion that much better locations can be found for deep prospecting than the one now under operation.

These operations will be assisted by the settlement of titles under the United States mining laws, many of the mine owners having already obtained their patents or taken steps toward that end.

The Juniata Consolidated mining company also own the large mills alluded to above. They were built by the Real del Monte and Antelope mining companies in 1863 or 1864. There is one small mill of five stamps belonging to Horace Marden & Co., which is started up and kept running semi-occasionally on small lots of ore (generally quite rich) taken out by "coasters," mostly from the old abandoned mines. More anon.

SANDFORD.

Aurora, Esmeralda Co., Nev., Jan. 6th, 1875.

SCIENTIFIC PROGRESS.

Is The Ether Matter.

Hydrogen passes through cast iron as water does through loose sand. The resistance which a cast iron ball would meet in its flight through an atmosphere of hydrogen would be scarcely appreciable. The difference in density between cast iron and hydrogen, though very great, is far from infinite; were it infinite, the resistance which either would offer to the passage of the other would be infinitely slight; to us nil. So with every other sort of matter in a medium infinitely more dense or infinitely more rare than itself. It is possible, therefore, to conceive, as Dr. Young suggests, of series of worlds of different orders, pervading each other, mutually unknown and unknowable, in the same space.

There is in this line of thought something more than purposeless speculation; and if there were not, one could hardly escape it in contemplating the theory of light now generally accepted by the scientific world, a theory involving conditions so astounding that nothing short of a new order of matter seems adequate to meet its requirements. Practically there could not be an hypothesis which would answer the requirements of a perfect hypothesis more completely than that which attributes the phenomena of light to undulations of a highly elastic medium pervading all space. It affords a reasonable explanation of every phenomenon in optics. More than that, it enables the investigator to anticipate effects which no eye has seen. Yet this most satisfying theory is based on the assumption that interstellar space which we have knowledge of, whether occupied by ordinary matter or not, is pervaded by something inconceivably more solid and elastic than steel.

Attempts have been made to dispense with the assumed ethereal basis of light by substituting therefor some excessively rare form of ordinary matter. To meet the requirements of the case, such a gas would have to be very rare indeed; at the same time it would have to possess an elastic force of at least a million million (1,000,000,000,000) times as great as the atmosphere at the earth's surface, conditions quite inconsistent with the main body of our knowledge concerning gases. If material, the physical basis of luminous undulations must be matter of an entirely different grade from anything else we know.

Any comparison between ordinary matter and anything so unlike it as the hypothetical ether must obviously be taken as suggestive rather than demonstrative; nevertheless the results of such comparisons give us, perhaps, as correct a notion of the physical basis of light as we are able to entertain. Our only clue to its possible qualities lies in the extreme rapidity with which light rays traverse it. It is understood that the velocity of wave motion depends, other things being equal, on the elasticity of the medium. Knowing the relative velocities of light and sound, Sir John Herschel calculated the necessary elasticity of the ether (in other words, the amount of force which the wave theory of light requires to be exerted at each point of space) as 1,148,000,000,000 times the elastic force of ordinary air at the surface of the earth. The atmospheric pressure is 15 pounds to the square inch; the corresponding ethereal pressure must therefore be about 17,000,000,000,000 pounds. The atmosphere counterbalances a column of mercury 30 inches high. Could it be demonstrated in a similar manner, the pressure of the ether would sustain a column of mercury six times as high as the sun!

These members give but an approximate idea of the enormous solidity of the adamantene something which the earth sweeps through at the rate of 1100 miles a minute without resistance. It pervades our bodies and we move about in it with perfect indifference. As Prof. Levens justly observes, all our ordinary notions of matter must be laid aside in contemplating conclusions like these; yet, "they are not more than the observed phenomena of light and heat force us to accept."

Regarded in the light of ordinary matter, the ether is impossible and incredible; as an extraordinary matter, or, as we have imagined, matter of a higher grade, it is consistent and reasonable. If we admit one such higher or lower grade of matter, the door is opened for the possible existence of an infinite series of them.

The contemplation of such possibilities may at least teach us not to be hasty in limiting the scope of the universe to elements such as we know.—*Scientific American*.

DANGERS OF BENZINE SCOURING.—M. Dumas, at a recent meeting of the French Academy of Science, stated that, in examining the process of scouring fabrics as usually practiced by cleaners of old clothes (washing in benzine), he had discovered a novel and dangerous cause of fire. Workmen engaged in this industry had frequently complained of the benzine becoming inflamed during the scrubbing; and in order to test the question, M. Dumas caused a piece of cashmere to be dipped in for a length of 18 feet. Every time the stuff partially emerged from the bath, while being rubbed between the hands, a sharp pricking sensation upon those members and on the face was felt; and finally sparks were emitted from the fabric, sufficient, if the scouring had been briskly continued, to have ignited the inflammable fluid.

Personal Equation.

It has been found by observation that there is a great variation in the power of different individuals to determine small intervals of time, or in the time occupied by them to become conscious of a fact passing before them. This is a matter of much importance in making astronomical observations—for instance the determination of the time of the exact contact or observation of heavenly bodies. The correction or averaging of this difference is called "Personal equation." Some years ago, at a meeting of the Albany Institute, Prof. Hough, the astronomer in charge of the Albany Observatory, read an interesting paper upon this subject, illustrating it by means of an instrument called a chronograph, which term, literally interpreted is a time-writer or an instrument for recording intervals of time. It consisted of a disk covered with white paper, and revolved by clock-work. From the center of the disk radii were drawn to the circumference, dividing the disk into equal parts, representing minute divisions of time. Over this revolving disk was placed a stylus, actuated by an electromagnet. A circuit-breaker was connected with this electro-magnet and held in the hand of the observer, whose personal equation it was desired to determine. Another disk, upon which a circular black spot was painted, was also caused to revolve by clock-work. Before it was placed in an opaque bar, which eclipsed the black spot at each revolution of the disk. The exact time at which the edge of the black spot reached the obscuration of the bar was automatically registered. The observer holding the circuit-breaker in his hand stood in front of the revolving disk, and was directed to operate the circuit-breaker in order to make the mark upon the disk the moment the black spot reached the bar. The difference in the time of registering by the observer and the automatic registering of the instrument constituted the personal equation. It varied considerably with different persons. We do not now remember what the maximum variation was, but we recollect distinctly that with some it was nearly double that of others. This difference in the power of determining precisely when an event happens, as seen by the eye, depends primarily upon peculiarities in nervous structure. It may, however, vary in the same observer from time to time. Professor Hough remarked, in his interesting paper, that he found his personal equation increased always when he felt ill.

THERMO-ELECTRICITY IN IRON SHIPS.—There is a curious point, says *Broad Arrow*, in connection with the deviation of the compass on board iron ships, which is now beginning to attract the attention of scientific men, and may therefore, perhaps, be new to some of our readers. It is now believed that some of the sudden and hitherto unaccountable changes in the deviation of the compasses of iron ships—which are often unsuspected until alleged as the only conceivable cause of the vessel running ashore—are the effects of an unequal and varying distribution of heat over the iron hull; for it is well known that electricity is generated in a metallic substance by heat applied in a certain way, and, in fact, there is a branch of electrical science called thermo-electricity, devoted to the investigation of phenomena of this kind. Sudden slight changes of compass deviation, not exceeding five degrees, have been noticed on board iron ships on the North American coast, and these are now attributed to changes in the hull, occasioned by the vessel passing from warm to cold water, and vice versa. The warm temperature of the gulf stream, taken in connection with the cold counter-current, is considered to be quite sufficient to account for many of the suspected compass errors on board iron ships.

THE ARTIFICIAL VANILLA.—We alluded a few weeks since to the fact of the discovery that the odorous principle of the vanilla beans could be obtained. We are now enabled to give the substance of the English patent that has been issued for this to Wilhelm Haarman, Ph.D., analytical chemist, Georgenstrasse, Berlin, Germany. Take, first, coniferine; or, secondly, the sap of plants mentioned above which has been purified or liberated from alumina or other impurities; or, thirdly, an extract of all those parts of the just-mentioned plants containing coniferine; or, fourthly, the products obtained from coniferine by means of fermentation, putrefaction, or similar action; and treat one another with oxidizing agents or such agents of similar action, such as bi-chromate of potassium and sulphuric acid, or any other peroxide, oxide, acid or salt, which produce the same effect. The product of the reaction in all these cases is artificial vanilla, which has been proved to be identical in all physical and chemical properties with the aromatic principle obtained by the extraction, etc., of the natural vanilla beans.

ASTRONOMICAL.—The astronomical discoveries of 1874, apart from those which may have been made by observers of the transit of Venus, were few and comparatively unimportant. Six asteroids were discovered, two by American astronomers, and three by Palisa, at Pola, near Berlin. Of the four comets discovered in 1874, that of Coggia only, was especially interesting. The meteoric shower of November 14th entirely failed for 1874. According to the calculations of some astronomers, no further return of this meteoric display in any considerable numbers can be expected till near the close of the century.

THE PHYSICAL FORCES ARE MODES OF ETHER PRESSURE.—Professor Challis, of Cambridge University, after long and exhaustive researches upon galvanic and magnetic action, concludes that the hydro-dynamical theory of action is almost correct. The theoretical explanation of galvanic and magnetic phenomena is to be sought by means of mathematical deductions. The author believes that the science of theoretical physics, laid down in Newton's "Principia," is by no means confined to physical astronomy, but comprehends the principles of all departments of natural philosophy which have relation to physical force. His conclusions on galvanic and magnetic action have been reached in conformity with Newton's rules and principles. The author's main conclusions, relative to the *modus operandi* of the physical forces, to which this system of philosophy seems to point, are: That they are all modes of pressure of the ether; that the forces concerned in light, heat, molecular attraction and repulsion, and gravity are dynamical results of vibrations of the ether; and that electricity and galvanic, and magnetic forces are due to its pressure in steady motions.

MECHANICAL PROGRESS.

Interesting Steam Boiler Experiment.

A correspondent of the *Scientific American* furnishes that journal with the following account of a late experiment made by him:

"With the intention of increasing the capacity of a steam boiler (horizontal, 42 inches in diameter and 18 feet long, with 32 tubes), I introduced some four inch tubes under the boiler, commencing just behind the bridge wall and running back the length of the boiler. These pipes had cast iron connections at the bends. I placed them eight inches below the bottom of the boiler, connected them at the back end of the boiler near the bottom, and attached the feed pump near the front, and fed with hot water. The first day they worked well and improved the boiler greatly in steaming capacity; but on the third day, just after starting up, with the first stroke of the pump, the cast iron end on the pipe where the feed pipe was connected burst with a loud report, and for a few seconds nothing but blue steam escaped, and finally water and steam. Thinking the trouble was in pumping in water so near the fire and bridge wall, I changed the connection, putting the feed pipe into the mud drum, and then letting the back connection stay as it was, making a series of circulating tubes. On firing up this time, I was alarmed by a succession of concussions or jars in the boiler that shook the walls; but by firing slowly, we got up steam without any accident. In an hour or two we noticed that the tubes nearest the fire and bridge wall were red hot, and blue steam was escaping from the joints of the connections on the ends of the tubes. We drew the fire and removed the tubes. We found a great improvement by the use of these tubes, and did not like to abandon the use of them. We are at a loss to account for the phenomenon of live steam being where we expected nothing but water. What is our remedy?"

In answer to this query, the *Scientific American* says: "The trouble seems to have been that the pipes got so hot that they made steam faster than it could be carried off, the circulation being imperfect. It will probably be necessary to use larger pipes, or to discard the return bends, to make the present arrangement successful. The same trouble has occurred with some forms of sectional boilers, whose use has been abandoned on account of the poor circulation."

Assembling in Machine Making.

The system of making the component parts of a machine or implement in distinct pieces of fixed shape and dimensions, so that corresponding parts are interchangeable, is known as "assembling." The term is, however, more strictly applicable to their fitting together, after being separately and accurately made, according to fixed patterns, and constantly compared by gages and templates which test the dimensions.

This system of interchangeability of parts was first introduced into the French artillery service by General Gribeauval about 1765. He reduced the gun carriages to classes, and so arranged many of the parts that they could be applied indiscriminately to any carriage of the class for which they were made. The system was afterward extended into several European services, and into that of the United States.

The first firearm attempted to be made on this system was the breech-loader of John H. Hall, of North Yarmouth, Massachusetts, 1811; of which 10,000 were made for the United States, \$10,000 being voted the inventor in 1836, being at the rate of one dollar per gun. Some of them were captured in Fort Donelson, February 16, 1862. They were probably the first breech-loading military arms ever issued to troops.

The extent to which the system of gages was carried with the Hall arm is not accurately known, but it is doubtless true that the principle was brought to a high state of system and accuracy by Col. Colt, of Connecticut, in the manufacture of his pistols. Among the most important of extensions of this principle has

been the making of special machines to fashion particular parts, or even special portions of individual pieces, so that each separate part may be shaped by successive machines, and hored by others, issuing in the exact form required.

This plan requires large capital, and will not pay unless a great number of like articles be required, but has been extensively introduced into this country, and from hence into England, and to some extent on the continent of Europe. All the Government breech-loading fire-arms are thus made. The greater number of the military arms of Europe and Egypt are thus made in the United States for the various countries. The Snider gun, a modification of an American model, is made at the Enfield Arsenal, England, on special machines made for that purpose in duplicate at the Colt works, Hartford, Connecticut. Pratt & Whitney, of Hartford, are just completing for Germany a full set of special machines and gages for the manufacture of the Minsler rifle, adopted by Prussia for the confederate German States.

The first watch made on this plan was the "American" watch, of Waltham, Massachusetts, the system extending down to the almost microscopic screws and other small parts. All the prominent sewing machines are so made; the same with Luth's knitting machine; and probably others. Many kinds of agricultural implements, including plows, harrowers, threshers and wagons, are made of interchangeable parts. The system has been carried into locomotive building; about seven grades of engines, it is understood, are employed on the Pennsylvania Central railroad, corresponding parts of a given grade being precisely similar, so as to fit any engine of the class. This is the American system of "assembling."—*Harper's Magazine*.

A Promising Invention—Re-rolling Steel Rails.

One of the objections which many railroad men urge against steel rails has been the difficulty of profitably utilizing them when worn out. This, though not a very formidable argument against them, when their great endurance is considered, constitutes, perhaps, a slight objection. Hitherto they have never been rolled when cut up and treated as an iron rail pile, as they do not weld. We speak now of Bessemer cast-steel rails; puddled steel headed rails are successfully produced, and certainly outwear the iron article; the so called silicon steel is but a variety of puddled steel. In a few years the large and increasing amount of Bessemer rails laid will be worn out, and must be replaced, thus rendering their proper utilization, in a secondary degree, a question of national importance. As scrap steel in the regular Bessemer manufacture they could not be disposed of; they cannot be melted alone in a furnace, as they burn; and their use in the Siemens-Martin process, in which a bath of cast iron is decarburized by the addition of wrought iron scrap, sponge, or steel scrap, would also prove a slow method of consumption. Re-rolling into a solid steel rail is the most rational and economical method, if it can be effected. It is barely possible that it is practicable with the aid of some flux, and one certainly worthy of trial has been invented by M. G. C. Henry, an analytical chemist of Burlington, Iowa. Its use has been very favorably considered by the Springfield Rolling Mill Superintendent, and it is giving good results in steel wire manufactured in St. Louis. At the Joliet Iron and Steel Works standard Bessemer steel, containing 0.35 of carbon, was welded perfectly, at a smith forge, no joint being afterward visible.

The function of a flux, in the welding process, is to form a fusible slag, by its union with the scale, or oxide, which forms upon the surfaces of heated iron. Borax, which is an acid salt of soda, has this property, and is commonly used by smiths; but its cost, about forty-five (45) cents per pound, precludes its use on a large scale. Mr. Henry thinks he can furnish the flux for \$15.00 per ton. It is a dark looking substance, and fuses at a light red heat. The low degree of heat, comparatively, at which steel burns, may alone account for the difficulty in welding it, and if a substance can be kept at the welding surfaces which shall remove this scale as rapidly as it forms, it would seem that at least the chemical difficulties were overcome. It is Mr. Henry's hope to enlist the attention of some rolling mill sufficiently to try the invention upon a steel rail pile, rolling the rails into B forms, regularly piling as in re-rolling iron, and by placing the flux on the top of the pile in the furnace, it is possible that in passing, as a certain quantity flows down the sides, and into the joints, it will make the pieces cohere sufficiently to turn over the pile. As the flux is not injured by heat, increasing the whole pile in a bath of it has been suggested. If this succeeds, mills could advantageously re-roll their second quality rails. It is to be hoped that some one may try the experiment.—*Western Manufacturer*.

HARDENING THE SURFACE OF STEEL.—Mr. G. Arnes, of Rochester, has proved that the surface of steel may be hardened, without hardening the mass of the metal, by placing the steel in a cylinder for example—upon an engine-lathe, and, while it is in motion, bringing into contact with it an emery wheel, rotating at a velocity of about one thousand eight hundred revolutions per minute.

Mining Stocks.

The stock market during the past week has not been in as firm a condition as for some time past. Prices have been comparatively low, and the dull weather has brought rather dull times for the brokers compared with the recent busy season. Whether the big break which was expected has come or not we do not know, but there has been a pretty heavy fall. There is no special change in the Comstocks and the *Enterprise* says of the mines. There is no change in the honanza mines or any other mines along the Comstock range except for the better, therefore the decline in stocks is charged by our people to the manipulations of big operators in San Francisco, who, it is supposed, have locked up all the money they could lay their hands upon and who have in this way and other ways cinched the market. Such of our people as own in the bonanza mines and have their stocks paid for are but little disturbed, as they feel perfectly safe so long as an earthquake does not come and swallow up the entire north end of the lead. As hundreds of persons—not only among our own citizens, but also from San Francisco and many other places—have visited and critically examined the great ore body, there can be no mistake about that. In regard to the richness of the ore, it is being ascertained by actual working in the new mill that it is even richer than was supposed by those who had examined it while it was standing in the mine. The drifts in the California, in the 1400 and 1500-ft levels are already in good ore and are fast advancing toward the very rich ore of the great bonanza, while the drift from the Gould & Curry, on the 1550-ft level, is 30 feet into California ground, and is being pushed ahead in the same rich ore as is found above on the 1500 ft level. At the Ophir end there is a constant and marked improvement, notwithstanding the many falsehoods that have been industriously circulated in regard to it in San Francisco.

LYTLE & HAWKES have been offered \$100,000 for their quicksilver claim in Cinnabar district, Trinity county. They have three large retorts in position at the foot of the mountain, with which they expect to produce 100,000 pounds of quicksilver daily. Dr. E. H. Pardee, of Oakland, has offered J. F. Doliffe \$10,000 for his mine, and negotiations are now pending. The Trinity company are in 85 feet with their tunnel, and have favorable indications. 11 men are wintering at Cinnabar. A great rush is expected as soon as spring opens.

A MAN named Mattock, from Carson, Nevada, has discovered an extensive cinnabar ledge in Pinto district, Inyo county. There have recently been several important gold and silver discoveries near this locality.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's Office, San Francisco.

WOODVILLE CONS. M. Co. Gold Hill, Nev. Jan. 14. Capital stock, \$12,000,000. Directors—W. Sherman, R. H. Sherwood, J. R. Lee, J. S. Wall and H. G. Maynard.

SPANISH S. M. Co., Jan. 14. Location: Flowery District, Nevada. Capital stock, \$5,000,000. Directors—George M. Pinne, D. L. McDonald, Jas. H. Crossman, James A. Pritchard and Michael Skelly.

MUTUAL INDEMNITY ASSOCIATION OF GRANGERS OF CAL., Jan. 14. Object: To secure to the families or friends of deceased members such pecuniary aid as shall shield them against want, by paying to the nominee of such member the sum of \$1,000, the same to be paid by assessment on surviving members. The Directors are: Josiah Earl, J. D. Blanchard, A. W. Thompson, E. Hallet, W. L. Ovarliser, J. A. Wilcox and C. J. Morley.

CALIFORNIA BANK G. S. & M. Co., Jan. 15. Location: Storey county, Nevada. Directors—John R. Spring, E. P. Brown, A. B. Perkins, Arthur C. Taylor and Sydney H. Horbert. Capital stock, \$10,000,000, divided into 100,000 shares.

BONANZA M. Co., Jan. 15. Location: Virginia City, Nevada. Object: To acquire water rights, ditches and flumes, and to develop certain mines. Directors—J. R. Grannis, H. W. Berryman, David Conkling, Richard W. Heath, Jr. and John Landers. Capital stock, \$10,000,000, divided into 100,000 shares.

ROCK BAR M. Co., Jan. 15. Location: Storey county, Nevada. Directors—E. J. Baldwin, R. H. Lloyd, Alex. MacAhee, A. Ross and M. Strass. Capital stock, \$60,000,000, divided into 60,000 shares.

POMTOSA QUICKSILVER M. Co., Jan. 15. Location: Santa Barbara county. Directors—Joseph G. B. Isham, S. Heynfield, Jr., Christian Rees, H. Bogart and S. Heynfield. Capital stock, \$10,000,000 divided into 100,000 shares.

NEVADA SILVER M. Co., Jan. 15. Location:

Monterey county. Directors—L. Goodwin, J. B. Winter, Thos. Eagle, M. Little and H. F. Pitts. Capital stock, \$6,000,000, in 100,000 shares.

NORTH LANEY BRYAN. M. Co., Jan. 15. Location: Storey county, Nevada. Capital stock, \$6,000,000. Directors—C. D. O'Sullivan, P. J. White, Robt. Sherwood, P. J. Cassin and Wm. Burley.

CONSOLIDATED BONANZA G. & S. Co., Jan. 19. Location: Ormsby county, Nevada. Directors—Calah S. Hobbs, John K. Hobbs, Wales L. Palmer, Israel W. Knox and Dyer A. Carpenter. Capital stock, \$5,000,000, divided into 100,000 shares.

ECREKA LAMP Co., Jan. 19. The object is to carry on a general mercantile business of buying and selling and manufacturing the self-lighting lamp and gas attachments. Directors—A. L. Day, C. P. Rank, J. T. Doyle, C. Mason and John Ben. Tungata. Capital stock, \$50,000, divided into 5,000 shares.

CAO S. M. Co., Jan. 16. Location: Virginia City, Nevada. Capital stock, \$10,000,000. Directors—S. H. Chamberlin, J. P. Moore, L. P. F. Waller, O. K. Britell and J. Weightman.

FRANKLIN GRAVEL M. Co., Jan. 19. Location: Placer county, Cal. Capital stock, \$2

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR COUNTY.

RUSH GRAVEL MINES.—Jackson, (Amador) Dispatch, Jan. 16: Messrs. Batterfield, Ryan, Pawling, and some four or five others of our citizens have been prospecting a gravel claim of about forty acres, about three miles below this place, which has every indication of enriching its owners. The paying gravel is from ten to forty feet thick, and extends over the entire 40 acres; and in prospecting, good colors were found in every pan. The owners are now making preparations for conducting water from the Amador Canal to the claim, in order to successfully and thoroughly develop the same. There is also another claim of forty acres, just below and adjoining the claim above mentioned, belonging to the Messrs. Morrow, which is said to be equally rich and valuable. We hope the owners of these mines will not delay the noble work of operating them on an extensive scale, as there can be but little doubt as to their extent and richness.

ALPINE COUNTY.

A QUESTION.—Alpine Chronicle, Jan. 9: The Leviathan mine having been relocated, the manager has submitted the case to the Commissioner of the General Land Office. The point raised is this: That the party in charge of the mine had orders to work it, and the manager supposed the work was going on, but it was not, and during the temporary absence of the person having charge, it was relocated. The question at issue is: Can employees thus sacrifice the interests of innocent parties?

MILL SITE.—On Saturday last a mill site was located on Silver Creek for the Occident, late Rippon mine.

RELOCATED.—On the 1st instant the Morning Star mine was relocated, and on the 2d, the Leviathan mine was also jumped.

COLUSA COUNTY.

ROADS.—Colusa Sun, Jan. 16: As soon as the weather will permit in the Spring, the Abbott and Buckeye Mining companies intend to build a good road from Sulphur Creek to Lower Lake. These mines will then be within fifty or fifty-five miles of Calistoga, and there will be a magnificent road all the way. The distance from Colusa to Sulphur Creek is about thirty-three miles, and thirty-five to the Abbott, and a miserable road to travel over. These mines will have to build a road to the Lake to get timber, and they will not build it on to the Sacramento Valley. At present Grizzly Cañon pretty much stops all travel beyond the Abbott, but once a good road made through that and away goes the trade of all that region, unless Colusa and those interested along the way build a good road to Sulphur Creek.

CALAVERAS COUNTY.

SAN BRUNO.—Calaveras Chronicle, Jan. 16: The work of putting an engine and hoisting works underground, in the San Bruno mine at Mosquito, is completed and sinking commenced. The engine is placed in the lower tunnel of the mine, about 500 feet in from the mouth, a large room having been hollowed out of the solid rock for its reception. The smoke-stack of the engine extends to the upper tunnel, a hundred feet or more above, and as there is a powerful draft between the two tunnels it is thought there will be no inconvenience from heat or smoke. The object is to work the mine by means of a shaft sunk from the lower tunnel, the engine being necessary to keep the works free of water and hoist the rock. The ore in the bottom of the tunnel is very rich, and the owners of the mine think it can be got out cheaper in the manner adopted than by driving a level to tap the lode lower. The machinery has not been started yet, its assistance not being required until the shaft reaches a considerable depth. The result of this novel mode of working the mine is awaited with interest.

WEST POINT DISTRICT.—The Mina Rica shaft has attained the depth of 165 feet, carrying a large, handsome vein. The vein inclines now in excess of the shaft and rich developments are looked for. A large force is employed at sinking, running levels, and stoping. The mill started last Monday. The Good Faith tunnel is being driven now at the rate of 7 feet every 24 hours. It is in 150 feet and the first of the five veins belonging to the property will be cut in about 40 feet farther. The Superintendent of the Josephine who was unfavorably predisposed in regard to the resources of this district, has been somewhat disappointed. The main shaft is now a few feet below water level, showing ore fully five feet in width. The ore looks splendid, showing handsome sulphurets of lead and iron, and plenty of free gold. A streak nearest the hanging wall and a streak nearest the foot wall, each one a foot thick, are estimated to yield not less than \$100 per ton; the balance, 3 feet, will mill in the neighborhood of \$20 per ton. Henry & Son have started their mill and are now steadily running on ore from their mines on Valentine Hill. The Zoatero has struck better ore than ever and the working force has been increased. The Haskins mine at Big Flat yields as rich ore as previous.

INYO COUNTY.

CINNABAR DISCOVERIES.—Inyo Independent Jan. 9: If Inyo county don't amount to some-

thing it won't be because it don't possess a sufficient quantity and variety of minerals. Now comes one Matlock, a mining man of Carson, Nevada, with the discovery of an extensive cinnabar mine in Pinte district, just east of Bishop creek. We have no particulars of the discovery, but as it is an established fact that that section has a number of very fine gold and silver mines, and now the quicksilver to work them right at hand, that end of the county ought to maintain its balance of power very easily.

PINE MOUNTAIN.—We have some very flattering reports of late developments and discoveries at Pine Mountain. Ebb Harrington, whose general knowledge of the mines of this region is very complete, and whose judgment is second to none, is confident this going to prove itself the "king district" of this entire country. Broder & Moffat fully intend to have a furnace in operation there in a short time. There is enough ore now on the several dumps to keep a furnace running a long time.

WIDENING.—Superintendent Todd informs us that the vein of rich black sulphurets in the lower levels of the Kearsage continues to widen as work progresses. We also hear that a heavy force will be put to work on this mine early in the spring.

ABOBS THE RIVER.—Mr. Messenger, of San Francisco, has been examining and reporting upon some of the old original mining locations in the foothills of the Inyo ranges across the river. May of these were of the case knife, atrata order, bearing exceedingly limited amounts of intractible ore, the location and attempted workings of which date back to the days of '63, when they built costly mills before obtaining the somewhat necessary mine. But all accounts agree that a mile or so back from the seams in the main mountains there is an extensive and rich mineral belt—so that by a little energy and perseverance there would have been no occasion for the fiscal downfall Owensville, Crispopolis, Bend City, San Carlos, etc.—all of which once lively places, before and during the Indian war are now numbered among the things that were.

MEDOCINO COUNTY.

Ukiah. Mendocino Democrat: About a ton of ore has just been shipped from the Wurfenburg & Burger mine, about a mile and a half from town, to San Francisco, for a thorough testing, so we may soon know fully how it is going to yield.

MARIPOSA COUNTY.

WASHINGTON MINE.—Mariposa Gazette, Jan. 16: We understand that the managers of this successful and valuable mine are about contracting for six thousand cords of wood, to be delivered at the mill during the coming spring and summer, this is an inducement to wood choppers and teamsters, and indicates business and prosperity for that locality.

NAPA COUNTY.

CALISTOGA.—Napa Gazette, Jan. 16: Work has been resumed in three tunnels of the Calistoga mine, but the mill is still closed. No ores are being hauled.

GOLD FROM FOSS VALLEY.—Gold bearing rock has been brought in from Foss valley that assays \$800 to the ton. If subsequent assays confirm this some little excitement will doubtless be raised.

NEVADA COUNTY.

PROVIDENCE.—Nevada Transcript, Jan. 16: The Providence mine has been for a year or more, trying to work out a bonanza in their mine, and have not found the end of it yet. The rock is not quite as rich as that in the California and Virginia Consolidated, but investors in the stock of the Providence are not in danger of having values fall several millions in a day; on the contrary the value is continually on the increase.

CONVENIENT.—The ditches which conduct water from the mountains to the towns and mines on their lines, over on the San Juan Ridge, are being utilized in floating flume blocks from the saw-mills above, to the mines below. These blocks are sawed above Columbia hill, and floated down the ditch to the points above, and near San Juan, thereby saving several miles of hauling with teams. We presume wood can also be shipped in the same manner. It saves an enormous bill of expense, and guarantees an inexhaustible supply of mining timber.

BEAUTIFUL BAR.—We saw a beautiful bar of gold, the result of a few days' clean up of one of our quartz mines. The bar was valued at \$9,000.

DEADMAN'S FLAT.—Foothill Tidings, Jan. 10: Deadman's Flat, two or three miles south westerly from this town is getting to be a lively flat for prospectors. McCook Brothers and Sanford have been getting good pay out of the Pittsburg mine out there for some time, but on Monday last they struck it richer than ever—\$80 to the pan. Mr. Wm. K. Spencer, the worthy telegraph agent here has a quartz claim near the Pittsburg, which it is said to resemble closely and which we hope to see panning out soon. A prospecting company started work on a new ledge near there a few days since and already have a good paying claim. Deadman's Flat may yet prove many a live man's raise.

That gold trap is in daily operation at the Empire mill and the inventor is sanguine of great success. No clean up has yet been made. [This item refers to the amalgamator which Mr. Lunbridge took up to Grass Valley to test at one of the mills. We will give the results of his work as soon as the new mine is cleaned up.—Ens. Press.]

PLACER COUNTY.

BOOTH.—Placer Herald, Jan. 16: The Eclipse mill has been pounding for some time on rock from the Booth mine, but a crack discovered in the bottom of one of the batteries, by which the amalgam was being wasted, caused the mill to be stopped for a short time, and necessitated a clean-up sooner than was calculated on. At the time of this clean-up there had been about 100 tons of rock crushed, from which was obtained 137½ ounces of gold. From the damaged battery, which is ½ heavier than the other, and must have crushed ½ more rock, there was obtained ¼ less gold, proving that enough was wasted to have raised the yield of the rock to nearly or quite \$30 a ton, which is decidedly an encouraging figure, especially when we consider the size of the ledge from which it is obtained.

BUSINESS.—The Greene mining company is rushing things in a business like way, which would lead us to infer that they have struck a bonanza. The old water-power mill belonging to the company is being torn down, and a fine new mill, to be driven by steam power is being erected near the hoisting works. With this improvement completed the company will be in a condition second, perhaps, to none in the county to work a quartz mine to advantage. And they have the mine to work. Between 200 and 300 tons of rich ore is already on the dump, awaiting the completion of this new mill.

SANTA CLARA COUNTY.

OUR MINERAL WEALTH.—San Jose Mercury, Jan. 16: It has long been believed that Santa Clara county possessed mineral wealth in some degree, but to what extent but little has been known from the fact that scarcely anything has been done towards the development of her mines. The belief of those who held that deposits of various kinds of ore could be found in our hills has been confirmed by recent discoveries. In addition to our valuable quicksilver mines, there are many traces of iron, lead, coal, and even gold and silver and other rich minerals. Of silver and lead a rich discovery has already been made, and there are places where there are fine prospects for gold, both quartz and placer. At Steven's creek, west of the valley, there are fine indications for the latter. At the head of the stream several Mexicans are now at work, and we are told by responsible parties that they are making on an average \$3 per day. If properly developed, we doubt not our mineral resources would contribute largely to our wealth.

SONOMA COUNTY.

VALUABLE DISCOVERY.—Sonoma Democrat, Jan. 16: About two thousand feet east of the Moulton mine, on J. A. Carrie's place, near Cloverdale, Tom Thompson, Dr. Ramie, John Field and others, have located a new mine which promises to be of great value. Tom Thompson, of Cloverdale, was the discoverer. In the gulch near the reservoir, the ledge is said to show very plain. The outcrop is pronounced by experts to be first-class, and the general impression is that the mine will prove immensely valuable.

QUICKSILVER LOCATIONS.—The law regulating the location of quicksilver claims provides that the greatest quantity that can be located by any one person, or by any association of persons, is fifteen hundred feet on the ledge, together with a surface location of three hundred feet on each side of the ledge. Parties intending to work a claim as a company should make their locations as individuals before forming their company, otherwise they will be limited to a single individual's allowance. A "discoverer" is entitled to no more than any other person, whether he has a family or not.

SIERRA COUNTY.

STRUCK IT RICH.—Mountain Messenger, Jan. 16: Jack Hardy has found rich diggings in his claim at Chapparral Hill. Jack deserves to be rewarded for years of unremunerative prospecting in this ground, and his many friends hope that he has at last struck a good lead.

PURCHASER.—J. Denoon, the superintendent of the Empire, Howland Flat, has bought the Phoenix mine, at Heppidam, for \$7,000. Jim, we trust this may prove a profitable investment.

PAYING WELL.—The Empire claim, at Howland Flat, is steadily turning out large amounts of gold, with no prospect of any cessation in the yield.

SISKIYOU.

GOLD PROSPECTS.—Yreka Journal, Jan. 2: Sam Jackson informs us that there is a hill near Maxwell's mill, at the head of Shasta valley, over all parts of which a gold prospect can be obtained. He further says there are very large quartz ledges in the vicinity. He thinks it not improbable that the hill would pay for working by hydraulic process. The matter is at least worth the attention of prospectors.

TUOLUMNE COUNTY.

LANT WASHINGTON.—Tuolumne Independent, Jan. 16: Shaft is now down 140 feet below the tunnel level, being at a point 300 feet below the surface. The rock looks better as they sink, and they have now a three-foot vein which prospects splendidly. The intention is to put the shaft down 200 feet further—making 500 feet from the surface; and if the rock at that depth shows as good as at present, the shaft will still continue its prospecting journey towards the center of the earth.

Nevada.

WASHOE DISTRICT.

OPERA.—Gold Hill News, Jan. 14th: Daily yield, 260 tons, taken from the 1300 and 1465-

ft levels, and the stopes and floors between. The north winze below the 1465-ft level continues in very rich ore, and the same may be said of the cross-cuts from the winze below this level, near the California line. The cross-cuts east from the 1465-ft level having gone considerably beyond the ore body are in the east country rock, with occasional seams of low grade ore, encouraging further explorations in that direction.

CONSOLIDATED VIRGINIA.—Daily yield, 425 tons, from the 1300 to the 1550-ft levels, exclusive. The ore breasts and stopes throughout never looked so well. The winze on the 1550-ft level has been sunk several feet since last report and continues in ore of very high grade. The north drift has been extended through the mine into the California some 35 feet, and continues in very excellent ore.

BELORE.—Daily yield, 400 tons, from the old ore sections. Nothing new to report from the winzes below the 1400-ft level; they all continue in good ore, and it remains for the drift, now being run from the main incline into the 1500-ft level to develop the true value of that level.

CALIFORNIA.—All the crosscuts on the 1400-ft level are looking exceedingly well, crosscut No. 1 being in a vein of ore of exceeding richness, assaying over \$300 per ton on the average. Judging from the levels below, this vein must be of great width. The ore in the various crosscuts on the 1500-ft level is identical in appearance and value with that found in crosscut No. 1, at the southern boundary. The ore in the face of the breasts in all the crosscuts is of a very high grade.

GEORGIA.—This mine lies between the Rock Island and Florida, upon the south side of the American Flat division of the great Comstock. It is an old location, and the old tunnel and winzes which have been lying idle for years past are now, under the new proprietorship, being reopened and worked, with a view to ascertaining the situation and dip of the ledge, preparatory to sinking a first-class working shaft.

JUSTICE.—The station at the fourth level of the main Justice shaft is well opened, and the connection with the drift north from the Waller Defeat shaft will be made very shortly.

JULIA.—Shaft still sinking at a lively rate, with the bottom in soft porphyry, clay and quartz. The south drift at the 1000-ft level shows decided improvement.

LEO.—The face of the tunnel is now in quite soft ledge matter. The ledge is over four feet wide, and steadily improving in character as headway is made. The prospects are very favorable for developing a rich body of ore soon.

EUROPA.—The winze below the tunnel, at the west side of the vein is now down 82 feet. At the depth of 100 feet it is proposed to crosscut east into the vein, to ascertain its value and dip at that point.

GOULD & CURRY.—The double winze sunk from the 1000-ft level has reached the 1700-ft level, and the work of drifting south to connect with the main incline is making good headway.

FLORIDA.—New shaft down 355 feet to-day, with the bottom in hard blasting rock, with fine looking stringers of quartz, dipping east and showing considerable improvement as farther sunk upon.

LOWER COMSTOCK.—Work is about being resumed on this old claim at Silver City, under the superintendence of Capt. Sam Curtis. A deep shaft is to be sunk, with a crosscut at the bottom through the lode. The old workings, although developing good bunches of ore giving high assays, were not deep enough for a good concentrated ledge.

CROWN POINT.—Daily yield, 500 tons. Nothing new in the crosscuts east at the 1500-ft level, or other prospecting movements at that or other levels of the mine. The main incline is sinking deeper very satisfactorily, and the 1600-ft level is being opened. The ore breasts and stopes of the old regular working levels are looking and yielding finely as usual.

CHOLLAR-POTOSI.—Daily yield, 40 tons. Car sample assays \$36 per ton, showing a slight improvement in the quality of the ore extracted. Prospecting operations going ahead as usual.

SILVER HILL.—The drifts both north and south at the third level show considerable improvement in the way of good pay ore.

WOODVILLE.—The new shaft is making excellent progress downward, the rock improving all the time, and works operating finely. The ore sections yield enough to keep the mill running steadily.

BUCKEYE.—The material being sunk through at the lower end of the incline indicates close proximity to the ledge.

LANT WASHINGTON.—The station for the 300-ft level is being opened. Staking the shaft below this point, however, will be suspended, but it will be continued down to see if good ore developments cannot be found, similar to that in the neighboring mine, the Justice.

HALE & NOBROSS.—Daily yield, about 100 tons, from the upper workings. On the 2100 ft level they are extending the cross-cuts west from the main incline, and making good progress.

BALTIMORE.—Work is temporarily suspended at the 750-ft level, but drifting will be resumed in a couple of days. The new and powerful hoisting and pumping machinery for this mine is on its way.

YELLOW JACKET.—The main incline is sinking at a good rate of progress, and the various prospecting drifts at the lower levels are going ahead.

Kern County Mines.

The Kern County *Courier* says: Not long after the era of quartz mining in this State it was found that an immense vein of this mineral extended from the southern confines of Mariposa to the northern limits of Amador county. In some places it was a solid lead of from thirty to seventy feet in thickness, and in some cases it ramified into numerous strata or branches separated by the country rock. Many parts of this vein, or vein system, was found to be rich, and all the valuable mines of Mariposa, Tuolumne, Calaveras and Amador are located thereon; and, in process of time it was found that all leads of gold bearing quartz that had no connection with this great mother lode were not permanent, and that, however rich they might be, they were sure to "peter" out. Experts in deciding upon the value of any new discovery made the matter of its connection with the mother lode one of the first subjects of consideration. Their judgment almost invariably conformed to the way this was decided. The fact that the mother lode was believed not to extend south of Mariposa long exerted a prejudicial influence to the mining interests of this county, preventing investments of capital adequate to their development, although it was admitted in no part of the State were external indications more favorable. But of late, as this country has been more thoroughly explored, this unfavorable judgment is found not to be sustained by facts. A great mother lode—a true fissure vein—has been distinctly traced, not only entirely across this county, but well into the counties of San Bernardino and Tulare, and if it is not an extension of that to the northward it is a similar and more extensive one, giving the same or even greater promise of permanence to mining operations on the line of its course. In this county several valuable discoveries have been made upon it, chief of which is the Big Blue or Sumner mine, at Kernville, but there are half a dozen others that will prove just as permanent and valuable in the same stage of development, at Hot Spring Valley, Walker's Basin and Tehachapi. An expert who has devoted much time to an examination of this great mother lode, recently gave it as his deliberately formed opinion that Kern county is the best gold mining region in the State. This we have always believed, and predict in less than five years there will be a half dozen mines in operation, as productive, extensive, and enjoying the same confidence of capital as that at Kernville, affording an insatiable market for home produce, and enhancing the value of farming lands to unprecedented figures. There is danger, as things look now, of an over-production of silver, but not of gold. We contemplate the vast deposits of this precious metal in Kern county with profound pleasure and hope, undisturbed by the most distant and intangible apprehension.

Waste.

Everybody knows that a great deal of gold and silver are, every year, wasted from our mines and mills. No process of working has yet been found which will save all of the precious metals. Improvements in saving have been made every year and perfection is being gradually approximated to, and may, some day be attained. But the waste has been very great. We venture to say that the tailings which overspread the farms below, and which the classical grangers call "slickens," are rich in gold and silver, not to speak of the quicksilver. It will pay somebody, some of these days, to work portions of these "slickens" for the metals they contain. A few days ago a gentleman who is sojourning here and who has a machine for saving gold, after one of our best mills has got done with its slimes, casts his eye on the big pile of sulphurets which have been put through the chlorination process of working. He thought there might be something of value in those cast aside sulphurets. He accordingly made a careful assay of some samples taken from one of these piles. His assay showed a value of \$15 per ton, in silver. The chlorination process has taken the gold out of those sulphurets but had left the silver in them. The same gentleman will make still further assays from those old sulphurets piles, with a view to extracting the silver that is in them, by some cheap and rapid process of working. Those sulphurets have been used somewhat extensively as a paint, and they make an excellent fire-proof paint, and yet they are worth about \$15 a ton for silver. That waste is likely soon to be corrected.—*Grass Valley Union*.

SCORPION.—This is a '59 location, and one of the oldest on the Comstock lode. It is situated north and east of the Union Consolidated ground, directly on the curve which this lode is supposed to make toward the east, at the north end, as shown by the recent developments in Consolidated Virginia, California and Ophir. There are 4,000 feet and 40,000 shares in the claim. The stock is concentrated in strong hands, and is quoted on the stock board at \$5 per share. A tunnel 1,200 feet in length has been run on the ledge, and crosscuts and winzes are now being made to determine the character and dip of the vein at that point. R. N. Graves has been appointed Superintendent, and the explorations now going on are for the purpose of guiding him on the selection of a suitable location for permanent works and a main shaft.

About \$16,000 was cleaned up at the Virtue mill, near Baker City, Oregon, during the month of December.

Alameda Coal Mines.

Livermore Coal Mine.

Work is still progressing in the tunnel approaching the main strata.

Black Hawk Mine.

The tunnel in this mine has progressed about forty feet, with very encouraging prospects. An offer has been made from San Jose of capital to develop this mine.

A New Mine.

A prospecting tunnel has been opened near Sonol, and a sample of the coal has been sent to San Francisco for testing its qualities.

H. A. Coal Mine.

The work on this mine is suspended for the present. The present issues of pro-rata shares are all taken up, and work will be again commenced in the spring. Mr. Wm. F. Cantley, a former superintendent of a mine in Pennsylvania, has made an examination of this mine, and reports that the shale covering is now being taken from the coal strata or bed. He speaks very favorably of the mine. He was so favorably impressed that he at once took sixty shares of the stock.

Contra Costa Mine.

Work is suspended on this mine preparatory to opening the tunnel 300 feet below the present prospecting tunnel. The prospects above warranting the extra outlay of a new tunnel.

Ethel Coal Mine.

This mine is located on a branch of the San Leandro creek, about a mile above the Chabot water works. A tunnel is being opened 16 feet wide and eight feet high; and although but a few feet into the hill, good prospects have been struck. The line of this coal strata has been surveyed, and passes directly through the H. A. and Black Hawk mines.

Grass Valley Mine.

Work in this mine is suspended until the application to the Government for condemnation of the land for mineral purposes is granted. Prospecting has been going on for the past week in the hill below San Leandro for coal deposits. Coal croppings have recently been discovered on Lucas and Cull's places, above Hayward. An offer has been made to Thomas Haller of a thousand dollars, to be taken in shares, if he will open the coal mine on his place.—*Oakland Transcript*.

THE ALTA gravel lead seems to be a pretty hard thing to follow up or find. Several nice fortunes have already been taken out of the deposits opened and worked thereon, and, considering that it is a well defined ancient river bed, and must be continuous above and below the part opened, there is every reason to believe there are several fortunes left. Clendenin, who has had an experience of over twenty years in this kind of mining, and has made the subject a special study for over twelve years past, says there are six more deposits on the Alta lead near Grass Valley, just as good as the No. 2 was, and he seems very certain that he has the knowledge of their whereabouts and can put men on the track thereof, so that no great waste of labor and money need be made in opening them up. As there has been much work thrown away in useless search for the channel and lead above and below the discovery claim, would it not be well to listen to the old man a little? He may not be so crazy on the subject as many put him up for. He has a claim himself that he is sure he can reach the canal in by running 100 feet more of tunnel, and being unable to prosecute the work alone, he offers a good lay-out to capital or labor to come in and help him through. He says there is a fortune for two in that claim, and a very small sum will enable him to reach it.—*Foothill Tidings*.

THE CONSOLIDATED VIRGINIA MILL.—Persons who visit the new mill of the Consolidated Virginia mining company, the sound of which is like music, and whose sixty stamps do not make as much noise as many five-stamp mills, should not confine their observations to the reducing works alone, but should pass down the hill and see the extensive preparations being made to save the tailings. Walls of earth have been raised around two large excavations, which are now blue lakes of liquid debris and pulverized ore, which is now continually flowing into them from the settlers. But the operations do not terminate here. Wooden sluices are being extended as far as the mouth of the old Latrobe tunnel, several hundred feet further down the hill where a large reservoir has been enclosed into which the refuse of the mill will flow and deposit what tailings it contains before it finally escapes down Six-Mile Cañon. A large force of men are engaged in completing the works and several teams are hauling lumber for their construction. A long trestlework is being built with a flat surface, divided by longitudinal strips of wood. Upon this blankets will be spread to catch the metal as the tailings flow over them. No experienced person can view without admiration the perfection of the new mill in every department and the close attention paid to detail. The building itself and the operations connected with reducing the ore occupy several acres of ground, every foot of which is economized for some useful purpose. When thoroughly completed the establishment will be superior in many respects to any other silver-bearing quartz mill in existence in this or any other mining country.—*Virginia Chronicle*, Jan. 12th.

Mica Mines in North Carolina.

The discovery of a valuable deposit of mica in Nevada recently, renders the following facts in regard to the only other mines known in this country, of interest. The *Scientific American* says:

Among the most interesting relics of the mysterious races of mound builders, who occupied the Mississippi valley previous to the advent of the more barbarous Indians, are numerous ornaments of mica. Like the weapons of hammered copper from Lake Superior, the shells from the Gulf of Mexico, the implements of Mexican stone and of Missouri iron, these plates of a mineral not found in this great valley, give a plain hint of the extensive commercial relations of these prehistoric peoples.

Mica was evidently mined in Western North Carolina, where their long abandoned workings have lately been reopened, and made the scene of a very modern enterprise. Seven years or so ago, a prominent citizen of North Carolina set some laborers to work in one of the ancient mines, in search of silver, supposing that metal to have been the one sought for by the original miners. A considerable quantity of mica was thrown out, but its value was not recognized until a sample, which had been sent to Knoxville, as a curiosity, was seen by a Mr. Clapp, who followed up the clue and leased the mine for its mica, and revived an industry which has added immensely to the wealth of the region. The mine is known as Blaylock's, about twelve miles from Bakersville, the county seat of Mitchell county. Four or five other ancient mines have since been re-opened in the same neighborhood, besides many new ones in the same and adjoining counties.

The mica trade has given general occupation to the population of Mitchell county, and has made money plentiful and thereby enabled the county to pay off its indebtedness, which it otherwise would have been unable to do. Mines have also been opened in Yancey, Heywood, Burke, McDowell and other counties. The business is still in its infancy, and the methods of mining are exceedingly primitive, yet the amount of mica produced is more than enough to supply the large and growing demand for the article. Dealers and manufacturers supply the mines with patterns ranging in size from 2 by 3 inches up to 15 inches square, according to which the mica is prepared for market. The dark or brassy colored mica brings the best price. Associated with this mica is an abundance of decomposed snow-white feldspar, which will, no doubt, be utilized in time, for the manufacture of porcelain.

THE NEW OREGON MINES.—Mrs. Heard received letters this first of the present week from her husband at the New Oregon mines on Rogue river near the mouth of Galice creek. He thinks the mines, without question, are extremely rich. Owing to the bad weather and lack of facilities of all kinds, but little work will be done in the way of developing them, till spring. However considerable work is being done in the way of taking out quartz to be crushed when mills shall be erected. One mill has already been ordered and will be up and ready for use by spring. The place is yet without hotels for the accommodation of people or stables for the accommodation of horses. Mr. Heard has taken up two claims on the ledge and a land claim in the vicinity for a farm. The country is, we understand, very mountainous, but has, notwithstanding, small bits of land here and there on the streams adapted to agricultural and grazing purposes. Mr. Heard's account of the richness of the mines, the prospects of the district, and of his own prospects in particular are quite flattering, but we hope more so than future developments will justify.—*Yreka Journal*.

SITKA MINES.—The Portland (Oregon) *Bulletin* says: J. H. Fisk, the well known assayer of this city, is corresponding with parties who have been engaged in prospecting and mining on the Sitka region during the past summer. From a letter recently received from Sitka we extract the following in relation to this wonderful mine lately found: "The discoverers of this mine went up to it in October, but there was so much snow they had to leave. As soon as the snow disappears I will accompany them. They seem to think it a permanent discovery. * * * On an island in front of this place, where they are prospecting for coal they have struck a two-foot ledge, containing copper and gold. This country is a mine of wealth, and I intend to remain with it."

AVAILANCES IN UTAH.—Dispatches from Salt Lake city, dated the 14th inst., say: Terrible snow storms are prevailing throughout the Territory. The cañons of Cottonwood are completely blocked with snow, and avalanches are occurring hourly, the citizens of Alta, Utah, fearing the destruction of the town from snow. They have guides out daily for the purpose of warning the people. The four men killed by an avalanche on Tuesday will be buried to-morrow, under the auspices of the Masonic fraternity.

CASTLE DOME district, above Yuma, in Yuma county, Arizona, is yielding considerable ore and bullion. Geo. Tyng, Esq., writes us on December 24th, that 160 tons of ore had just gone to the mouth of the river for shipment to San Francisco, and that 200 tons more were ready for shipment by the next steamer.

Quartz Mining on South Yuba.

From a correspondent near Washington in this county we learn that the well-known Lindsay mine in that vicinity has lately been incorporated under the name of the Fall Creek company, with Capt. Kidd Bell and others as Directors, and a capital stock of \$5,500,000. It is reported that they will remove the mill and works from the top of the hill down near the river, which will give them 1600 feet of ground above the tunnel to their present works, and our correspondent thinks if they do and select the right point and open the mine well, there is no trouble about making big dividends from this property. South of this is the Yuba mine, owned by F. A. S. Jones, which is looking splendidly, having rich rock at the surface for 400 feet, and a tunnel driving in to open it up. North and south on the same lode are several locations of much promise, which our correspondent says he will mention at some future time. Still farther south than any previous locations a rich lead of quartz has lately been discovered by J. F. Smith. His ledge is about two feet thick, and the rock will average eighty dollars per ton. It is stated that it will produce \$200 rock, and our correspondent says "so it will, but the average is the thing, and what it will mill, and this can be put at eighty dollars."

The California mine near Washington, is going on nicely. The Canyon Creek is doing a little, and has the appearance of good rock, but the mill has not started up yet. The tunnel on the Blue Tent ditch continues in hard rock, but is expected to be through in two or three weeks.—*Foothill Tidings*.

Cheap Boxes for Plants.

The cost to the amateur of handling and potting plants in the early stages of their growth is trifling; but to the nurseryman, who carries thousands of horticultural nurslings through from one period of growth to another, the expense of boxes and pots is considerable. We learn, however, that some of the nurserymen of Capay valley have adopted a device which almost does away with this expense. One of them, while on a visit to Swan & Co.'s Union Box Factory had his attention called to a method by which boxes may be formed by simply folding a scored piece of board so as to form a box with four sides, the ends lapping, and requiring nothing but a string tied about it to constitute a box sufficiently strong for nursery purposes. When the plant is to be transferred from this to a larger box or to the garden, by simply cutting the string and unfolding the sides, the plant is disengaged without disturbing the earth by sliding.

Some of these scored pieces were recently examined by us at the above named factory. They were about a foot in width and long enough to form a box 4x4 inches. This is to be cut into three sections; each being 4 inches square; though the size, of course, can be varied; and being only the thickness of the common strawberry box they can easily be cut into sections with a pocket knife. The factory furnishes these boards, scored and ready for folding, at one cent each. Thus the purchaser has the material for three boxes at the cost of one cent; and in a condition as convenient for transportation as a package of pasteboard.

THE NEW SHAFT.—The new California and Consolidated Virginia shaft, better known as the C. and C. shaft, although recently commenced, already begins to present the appearance of regular hoisting works. A large building has been erected over its mouth, an engine is in full operation, the shaft is down a distance of 75 feet, and a dump-pile extends from 25 to 30 feet down the hill, and is in miniature that which it will become when the shaft has been sunk to the required depth. There is plenty of room to the eastward to extend it, even should it in future times equal the proportions of the Savage dump or that of the Gould & Curry. A large amount of lumber is being hauled upon the ground for the purpose of timbering the shaft, and the neighborhood exhibits a lively appearance. Three months ago it was one of the most barren localities about town, but now an army of workmen are engaged in the vicinity, the scream of steam-whistles and noise of engines are heard, teamsters are making new roads through the sagebrush, and a portion of the city which was heretofore deserted and without attractions of any kind, has suddenly sprung into a new existence.—*Virginia Chronicle*.

SMELTER DESTROYED.—The Helena *Independent* says: On Friday evening, about seven o'clock, the furnace situated about two miles from Jefferson City, was discovered to be on fire, and as the wind was blowing a gale at the time, the whole building was soon enveloped in flame, and in a shorter time than it takes to write this article, all that was left of the Jefferson smelter was a heap of smoking ruins. Many of the surrounding miners were working in the expectation of selling their ores to Mr. Nowlan, and with some of whom we believe he had contracts. To these parties it will prove a great disappointment.

THE CORRECT WAY.—We understand that a movement is on foot to thoroughly test the worth and value of the Santiam mine during the present season. For 15 years this section has been scratched over after a fashion, resulting as could be expected.—*Portland (O.) Bulletin*.

GOOD HEALTH.

Treatment of Diphtheria.

The following rules for the prevention or extirpation of diphtheria form the concluding sentences of a report submitted recently by Dr. Stephen Smith, of the U. S. Board of Health.

Precautions—The Dwelling or Apartment.

Cleanliness in and around the dwelling, and pure air in living and sleeping rooms, are of the utmost importance wherever any contagious disease is prevailing, as cleanliness tends both to prevent and mitigate it. Every kind and source of filth around and in the house should be thoroughly removed; cellars and foul areas should be cleaned and disinfected; drains should be put in perfect repair; dirty walls and ceilings should be lime washed; and every occupied room should be thoroughly ventilated. Apartments which have been occupied by persons sick with diphtheria should be cleansed with disinfectants, ceilings lime-washed and woodwork painted, the carpets, bedclothes, upholstered furniture, exposed many days to fresh air and sunlight. All articles which may be boiled or subjected to high degrees of heat should be thus disinfected. Such rooms should be exposed to currents of fresh air for at least one week before re-occupied.

Well Children.

When diphtheria is prevailing, no child should be allowed to kiss strange children, nor those suffering from sore throat (the disgusting custom of compelling children to kiss every visitor is a well contrived method of propagating other grave diseases than diphtheria) nor should it sleep with or be confined to rooms occupied by, or near articles (as toys taken in the mouth, handkerchiefs, etc.) belonging to children having sore throat, croup or catarrh. If the weather is cold the child should be warmly clad with flannels.

When Diphtheria is in the Family.

The well children should be scrupulously kept apart from the sick, in dry and well aired rooms, and every possible source of infection, through the air, by personal contact with the sick and by articles used about them in their rooms, should be rigidly guarded. Every attack of sore throat, croup, or catarrh, should be at once attended to. The feeble should have invigorating food and treatment.

Sick Children.

The sick should be rigidly isolated in well aired (the air being entirely changed at least hourly) unlighted rooms the outflow of air being, as far as possible, through the external windows by depressing the upper and elevating the lower sash, or a chimney heated by a fire in an open fireplace; all discharges from the mouth and nose should be received into vessels containing disinfectants, as solutions of carbolic acid or sulphate of zinc, or upon cloths which are immediately burned, or if not burned, thoroughly boiled or placed under a disinfecting fluid.

WHY AMERICAN WOMEN ARE UNHEALTHY.—If we trace the history of New England back a few generations, we find a stalwart race of mothers and grandmothers; and even now there are specimens of these, healthy, active, happy, of ages varying from three-score-and-ten to one hundred years; and if we trace the history of American women from the landing of the Pilgrims to the advent of Dr. Clarke's book, we shall find the degeneracy exactly corresponding with the increase of sedentary habits, fashionable dress, gormandizing on indigestible food and condiments, forced and precarious development, sensational literature, and dosing and drugging for the multitudinous ailments consequent on a mode of life which has so little of nature and so much of the preternatural about it. Until the children and young women of America return to the more normal ways of their ancestors, they will go down, down, in the scale of vitality, with, or without co-education, or school education of any kind. Co-education is one of the measures that will exercise a saving influence; but alone it will not arrest the deteriorating tendency. This requires a thorough indoctrinating into the laws of hygiene and their strict application to practical life. In this, and in this only, is the hope, not only of American women, but of American men, and, indeed, of the human race.—*Phrenological Journal*.

DIPHTHERIA A MALARIAL POISON.—The microscope demonstrates that typhus and typhoid fevers and all their genera, diphtheria, etc., are generated by malarial poison. New York is given as an example, where the sewers and stoves murder 18,000 people annually; the death rate being 34,000 whilst the normal rate should be but 11,000. The remaining 5,000 are thrown into other channels of murder and suicide. The same evil prevails throughout the territory we have mentioned, and we do not believe the *Manufacturer* can do a greater service to its readers than to urge reform in stoves, sewers and ventilation.

MEASLES.—The *Callistoga Free Press* understands that this epidemic is prevailing there, and has become quite wide spread. It is mostly confined to children, and that which has, thus far, made its appearance, is of a mild type and readily yields to care and suitable attendance.

Scarlet Fever and Dyptheria.

The prevalence of scarlet fever, and dyptheria, as an epidemic in many sections, induces us to call attention to the use of bromo-chloralum, as an agent for purifying the air of the dwellings and sick rooms, by neutralizing and destroying at once all noxious odors and gases, as well as germ of disease, and putrescent particles floating imperceptibly in the air.

It is a concentrated solution of aluminum chloride and bromide, inodorous and non-poisonous and after repeated trials, has been found to be both agreeable and potent. It promptly absorbs and decomposes all ammoniacal and noxious gases, and renders the atmosphere and surrounding objects sweet and wholesome. It has been tested in such a variety of cases with such uniform success, that we feel warranted in recommending it to the public for general use, in all places or circumstances that give rise to unhealthy, bad odors.

A striking merit of bromo-chloralum is, that it operates by removal and not by creating an odor greater than the one sought to be removed. Can be applied in the most simple manner, directing it according to the object or locality to be purified. Indeed one great element of its success is the capability of free diffusion, causing it to purify the air as well as the walls, ceilings and floors.

For scarlet fever and other contagious diseases suspend towels in the room moistened with it diluted. Use freely on all bedding and in the chamber utensils, previous to use, as by this method the poison of excretions is neutralized.

Also when the throat is ulcerated or inflamed, gargle with it diluted one to ten of water. We are advised that patients feel much comfort from the use of a dilution of one part to 12 or 16 of water as a wash; all speak of its soothing influence when applied to the burning, itching surface. It neutralizes the poison, limits the spread of the disease. Attendants should use the same freely upon their clothes and person.

For diphtheria, sore throat, etc., dilute one part to ten of water, or stronger according to circumstances, and gargle the throat when advisable, also swallow 5 to 10 drops in a teaspoonful of water. The general directions as to purifying the air of the house and room should be observed fully.—*Journal Materia Medica*.

CASTOR OIL AMONG THE CHINESE.—A writer in the *Journal of Applied Science* states that castor oil has so little effect on Chinese intestines that the Celestials use it habitually in cookery.

USEFUL INFORMATION.

WHY NOT EAT OYSTERS IN SUMMER?—According to the popular notion; which, in the main, is correct, the spawning season of the oyster embraces those months which have not in their spelling, namely: May, June, July and August, the four warm months in the year. The fact is, that oysters generally, do their spawning during these four months; but a few are liable to spawn whenever the water is warm enough, and large numbers pass through the year without spawning; and these, were it not for the difficulty of assorting them, would be available for food at any time. But the prejudice is universal against their use during the summer months. That they are not in as good condition then as during the cooler months, is reasonable to suppose; but that they are all necessarily unwholesome in the warm months, is far from being proved. In business phrase, oysters in spawning time are said to be 'milky.' This means the presence of an opaque fluid in considerable abundance, and which has to do with the wants of its young—perhaps, remotely, a sort of fluid of amnion.—*Popular Science Monthly*.

A NEW "RATESANE."—And now the flowering plant "asphodel," is to drive away the rats wherever they may be. This is a perennial, but where it is to be obtained we know not. Perhaps at some of our seed-stores. We, however, would not advise the destruction of all the cats until after a thorough trial and proof of the efficacy of the new "exterminator."

[The asphodel is a fine garden bulbous plant, much cultivated in Europe. It has a stem about three feet high, thickly covered with three-cornered yellow leaves. Its flowers are of a yellow color, reaching from near the base to the top of the stem. The ancients were in the habit of planting the flowers in burial places, to afford nourishment for the Shades of the dead. It is said that the bulbs of some varieties of this plant, when dried and ground to powder, make an excellent glue.—*Eds. Press*.]

LEATHER FROM TAPE.—A method has been patented in France for preparing leather from tripe and other animal membranes, the leather thus made to be used for glove making, etc.

ANTS, CAICRETS, and other insect annoyances may be driven from their nests and holes by sprinkling carbolic acid diluted with water around these places of resort.

THE Popular Science Monthly ridicules the idea that oysters shouldn't be eaten in the months that haven't an r in them as well as in other months.

ARTIFICIAL FURS.—M. Tassand, of London, suggests an ingenious way of preparing the hair or fur of animals for use without employing the skin. The process consists in first soaking the fur in lime water to loosen the adhesion of the hairs. After washing and drying, the pieces are stretched upon a board, fur side up, and a solution of glue laid over it, care being taken not to disturb the natural position of the hairs. After the glue has hardened, the skin may be pulled off, leaving the ends of the hair exposed. The latter are then washed with proper substances to remove fat, bulbs, etc. An artificial skin of gutta percha, or other waterproof substance, is next laid on top of the glue and allowed to dry, so as to form a continuous membrane, when the glue is washed out with warm water. These artificial skins are entirely free from any animal odor, and are more durable, lighter, and more pliable than the natural ones.

CEMENT FOR ATTACHING LABELS TO METAL.—Many of our lady readers have no doubt been much troubled in putting up fruit, to make the labels stick to the tin cans. The *Medical Journal* says that a paste made as follows will meet the case: Ten parts tragacanth mucilage, ten parts honey, and one part flour. The flour appears to hasten the drying, and renders it less susceptible to damp. Another oment that will resist the damp still better, but will not adhere if the surface is greasy, is made by boiling together two parts of shellac, one part of borax, and sixteen parts water. Flour paste, to which a certain proportion of sulphuric acid has been added, makes a lasting cement, but the acid often acts upon the metals.

WEATHER OBSERVATIONS.—When you wish to know what the weather is to be, go out and select the smallest cloud you can see. Keep your eyes upon it, and if it decreases and disappears, it shows the state of the air which will be sure to be followed by fine weather; but if it increases in size, take your great coat with you if you are going from home, for falling weather is not far off. This reason is this: When the air is becoming charged with electricity you will see every cloud attracting all lesser ones towards it, until it gathers into a shower; and, on the contrary, when the fluid is passing off or diffusing itself, then a large cloud will be seen breaking to pieces and dissolving.

THE FIRST PATENT.—It is said that the first patent issued by the United States was granted to Samuel Hopkins on July 30, 1790, for the manufacture of pot and pearl ashes. The third was to Oliver Evans, of Philadelphia, so famous for inventions in high pressure engines, of whose inventions President Jefferson remarked that "it was too valuable to be covered by a patent, and there should be no patent for a thing no one could afford to do without after it was known." This was in December of the same year in which Hopkins obtained his patent. For many years after this date the Patent office was but a clerkship in the State department.

PAINTING OLD BUILDINGS.—An inexpensive but durable method of painting old buildings is as follows: First give them a coat of crude petroleum, which is the oil as it comes from the wells, and which can be procured for four or five dollars per barrel. Then mix one pound of "metallo paint," which is brown or red hematite iron and finely ground, to one quart of linseed oil, and apply this over the petroleum coat. The petroleum sinks into the wood, and makes a groundwork for the iron and oil paint. The color of the iron paint is a dark reddish brown, and is not at all disagreeable; it is a color not easily soiled, very durable, and is fire-proof.

MINUTENESS OF FUCHSIA SEEDS.—A gentleman recently visiting a fuchsia house (hot house) in Europe was asked to guess the amount of fuchsia seed gathered in one year from the house—10 by 30 feet in size. Twenty, ten, and even as little as one pound were suggested, but the fact proved that the entire product was only one quarter of an ounce. The *Garden* says that Mr. Cannell's specimen fuchsia-house, 30 feet by 20 feet has not yet afforded him a quarter of an ounce in one season. One may infer from these facts how fine the seed is.

GILDING AND SILVERING SILK THREAD.—In a process that has been patented in England, gold or silver leaf is rubbed on a stone with honey until reduced to a fine powder. The silk thread is soaked or boiled in a solution of chloride of zinc, and, after being washed, it is boiled in water with which the gold or silver powder has been mixed. When washed and dried it will be found coated with a fine layer of gold or silver, which may even be polished in the usual manner.

VARNISH THAT WILL ADHERE TO METAL.—In order to make alcoholic varnish adhere more firmly to polished metallic surfaces, A. Morell adds one part of pure crystallized boracic acid to two hundred parts of varnish. Thus prepared it adheres so firmly to the metal that it cannot be scratched off with the finger-nail; it appears, in fact, like a glaze. If more boracic acid is added than above recommended, the varnish loses its intensity of color.

TO PRESERVE COLOR IN DRIED FLOWERS.—To preserve the natural color in dried flowers, lay them when fresh into alcohol for a few minutes—they will fade at first—but recover their color.

DOMESTIC ECONOMY.

Useful Recipes.

EDITORS PRESS:—I send you some cooking recipes which we have tried and found very good and they are so simple that even a dyspeptic could not object to them:

BROWN BREAD.—1 cup of corn meal, scalded; 1½ cups Graham flour; 1½ cups white flour; ½ cup of syrup or molasses; 2 tablespoonsful brewer's yeast, or two-thirds cup of home-made yeast; a little salt and water, enough to make a stiff batter. Set in a warm place to rise, and when light bake in a hot oven in muffin rings or loaves, the muffin rings are best.

TAPIOCA PONDING.—1 cup of tapioca and a teaspoon of salt; put in three large cups of warm water and soak three or four hours; pare and core enough apples to cover the bottom of a pudding dish, and fill the hollows where the cores were taken out, with sugar and a very little nutmeg or cinnamon; pour the tapioca over the apples and bake three-quarters of an hour. This recipe is for apples that cook easily. Serve with sugar, cream, or milk or a warm sauce.

CREAM CAKE.—1 cup of sugar; 2 eggs; 1 tablespoon of butter; heat together with a little salt; 4 tablespoons of water; 1 teaspoon of yeast powder mixed with the flour, flavor with lemon. This makes two cakes. The cream is made with one-half pint or more of milk. Heat the milk in a dish in a kettle of water and thicken with two eggs, a little salt and sugar, beated together, and one tablespoon of corn-starch mixed in a little cold milk, stir well and let it just come to a boil. When cold flavor with lemon, cut open the cakes and put the cream between the pieces. L.

Santa Cruz.

WATERED BUTTER.—In the course of some investigations made by Professors Angell and Hehner, England, out of analyses of fifteen samples of butter which were determined by them, twelve of the samples, which were undoubtedly good butter, contained 6 to 13 per cent. of water; the astonishing quantity of 42.3 per cent. was found in one sample from London, or an excess of about 32 per cent. of water, for which Londoners pay from 32 to 48 cents per pound. Another butter from the same place had 24 per cent., these high ratios being due to the fact that the butter had been treated with milk. On the other hand, a sample purchased in Ventnor was found to contain under 4 per cent. of water, and according to the authors it contained 50 per cent. of foreign fat. The authors also found that genuine butter spread out on sheets of paper and exposed for a week to the air in the laboratory became, so far as the senses could judge, indistinguishable from tallow.

BEAN PORRIDGE.—Parboil the beans as if for baking; drain and put them in the liquor. This needs the salt earlier than the soup, and no flavor save the beans. Boil until the beans become broken and tender, and then add hulled corn, or Indian meal, or both. Stir in the meal carefully, not to lump, or get too thick. When it is well cooked and seasoned properly, take a large spoon, and stir thoroughly together. You will have a luscious dish, and "better when nine days old," says the proverb.

A slice of a nice piece of pork is a relish in either of the above dishes, for the meat should be kept for shortening, as there is usually enough left in the bones for the soups. I never knew an edge-bone to cost more than ten cents, often only six cents per pound. Two or three good meals and pies can be obtained from one. The coming winter some one may like to try it.

MAKING COFFEE.—A correspondent gives this receipt for coffee: Use about one tablespoonful for each person, and one egg mixed with it. Place this in a coffee-pot, put in a little cold water, and then the desired amount of boiling water; place upon the stove and let it come to a boil. If no egg is used, it should never boil over a minute. If an egg is used, it may boil two minutes, when it will be ready for use. The coffee-pot should be as close as possible, so as to retain the flavor. The object of using a little cold water is to give a little time for hot water to extract its virtues before it boils.

ROYAL FRUIT CAKE.—Five cups of flour, five eggs, one and one-half cups of sugar, one cup of molasses, one and one-half cups of butter, one teaspoonful of saleratus, one-half a cup of milk, two pounds of chopped raisins, three pounds of currants, one and one-half pounds of citron, two tablespoonfuls of cinnamon, one nutmeg, two teaspoonfuls of cloves. This is a splendid receipt. I have some cake now that I made a year ago, and it is nicer now than when first baked.—*The Household*.

GROUND RICE GAUDEL.—Daisy Eyebright gives the following: "Boil one tablespoonful of ground rice, rubbed smooth with a pint of cold water, in a pint and a half of milk, with a bit of cinnamon and lemon peel. Sweeten slightly, or season with salt."

BAKED EGGS.—Beat up six eggs, one tablespoonful of flour, six of sweet milk; melt your butter in the frying-pan; when hot, turn the whole in, well-beaten, and bake in a hot oven

San Francisco:
Saturday Morning, Jan. 23, 1875

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Hydraulic Mining in California; Nitro-Glycerine Compound; A San Francisco Stone Front, 49. The Mining Interests in 1874, 56-57-60.

ILLUSTRATIONS.—Welch's Pinking Iron; Nitro-Glycerine Igniter; Mixer for Acids and Glycerine, 49.

CORRESPONDENCE.—Jottings from Tyho, Nevada, Esmeralda, 50.

SCIENTIFIC PROGRESS.—Is the Ether Matter? Dangers of Benzine Scouring; Personal Equation; Thermo-Electricity in Iron Ships; The Artificial Vanilla; Astronomical; The Physical Forces are Modes of Ether Pressure, 51.

MECHANICAL PROGRESS.—Interesting Steam Boiler Experiment; Assembling in Machine Making; A Promising Invention—Re-rolling Steel Rails; Hardening the Surface of Steel, 51.

MINING STOCK MARKET.—Thursday's Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of Stock Market for the Week, 52.

MINING SUMMARY.—From various counties in California and Nevada, 53.

GOOD HEALTH.—Treatment of Diptheria; Why American Women are Unhealthy; Diptheria a Malarial Poison; Measels; Scarlet Fever and Dyphtheria; Castor Oil Among the Chinese, 55.

USEFUL INFORMATION.—Why not Eat Cysters in Summer? A New "Bathhouse" Leather from Trippe; Artificial Furs; Cement for Attaching Labels to Metal; Weather Observations; The First Patent; Painting Old Buildings; Minuteness of Fuchsia Seeds; Guiding and Silvering Silk Thread; Varnish that will Adhere to Metal; To Preserve Color in Dried Flowers, 55.

DOMESTIC ECONOMY.—Useful Recipes; Watered Butter; Cakes; Making Coffee; Royal Fruit Cake; Ground Rice Gruel; Baked Eggs, 55.

MISCELLANEOUS.—Kern County Mines; Waste; Scorpion; Alameda Coal Mines; The Consolidated Virginia Mill; Mica Mines in North Carolina; The New Oregon Mines; Silks Mines; Avalanches in Utah; Quartz Mining on South Yuba; Cheap Boxes for Plants; The New Ship; Smelting Destroyed; The Correct Way, 54. A Chapter of Tule History; Staten Island; Mining Accident; Arizona Mines, 58.

A San Francisco Stone Front.

The Safe Deposit company's building now being erected on the southeast corner of California and Montgomery streets, bids fair to be one of the finest in appearance in the city. It is to be four stories high with 137½ feet frontage on Montgomery, and 69 feet on California street. Its whole front will be of Frear stone with handsome ornamental projections and foings. Last week we visited the Frear manufacturing works, and found over 51,000 cubic feet of stone already manufactured for this building. The total weight of Frear stone required for the building will be 450 tons.

Coarser sand than usual has been used in the manufacture of this particular stone, which gives it a nearer resemblance to natural stone than any of the Frear we have before seen. It is believed that this improves its texture as well as its appearance.

We cannot here describe the various ornamental designs which will appear in the building. As arranged in parts about the works, the ornamental pieces seem almost innumerable. They also appear to be in good taste, and when erected the structure will form an entirely novel piece of architecture in San Francisco. The columns are rounded. Fluted, Corinthian and composite capitals are employed. The window heads are truly ornamental and very bold in relief. On the right of the grand corner window will rest a stone relief design, representing mining, embracing the pick, pan, spade and bar, etc., on the left, agriculture, with plow, wheel, rake, grape, etc. Wm. Patton is the architect. We should like hereafter to give a fuller description of his designs.

By the manufacture of this artificial stone we shall see a massive and beautifully wrought block arise during a few months in our midst that would otherwise have been years in building at more than double the cost. By the erection of this structure the Frear stone company takes a front stand in our city and in our home manufactures. We shall be pleased to see them maintain it. They have some of the best business partners in San Francisco in the enterprise. Their Superintendent is indefatigable in his labors. Their works are a living example of home industry that ought to be liberally duplicated in this State.

A large quantity of stone is also being turned out by the Frear company for the front of a new building on Sansome street. Portland cement is used exclusively in the manufacture of Frear stone on this coast. Over 2,600 barrels are now held in store by the company. Artizans and others who look with pride on such works will find the present a favorable time to call on Capt. Cushing at the manufactory on Bluxome street, near Fourth.

The Mining Interests in 1874.

The miners of the Pacific Coast never had more cause for congratulation in finishing a years work than they had in completing that of 1874. The year has been one of hard work and well earned profits, and the miners may well look with pride on the array of figures representing the result of their labor. We have heard of successful mining ventures on every hand, and fewer failures than usual. This is due to the fact that the people on this coast are fast awakening to the idea that they must engage in mining, as they do in any other business, and invest their money without excitement and with judgment and forethought. The day has long gone by when a man can come to San Francisco with a few lumps of quartz and sell a claim for thousands of dollars. He must now bring the proper papers to prove his ownership, location, etc., and then an expert will accompany him to the mine and examine it in the interest of the purchasers. It takes several months, as a general thing, to dispose of a mine in these days which, a few years ago, could have been sold in a week. This is a fact in which we really ought to congratulate ourselves as it shows that those who invest their money in mining property only do so after a thorough examination and mature deliberation. They will therefore work their property in a more legitimate manner, and trust less to stock-jobbing operations.

This matter is one of more importance than many suppose and exercises a potent influence on the mining interests. With mines scattered all over the country, worked properly and with due regard for economy, money can be made rapidly. It will encourage capital to help out labor and encourage the prospectors in their work of bunting up new mines.

A large number of new mines were opened up last year of which we will hear more in the future. In California and Nevada, moreover, particularly the former, we hear of many old abandoned mines being taken up again and reworked. In many cases costly works were put up years ago and mines opened by inexperienced men, which were afterward abandoned as failures. Many of these old locations are now being worked by competent men and made to pay well.

The year 1874 has been marked, perhaps, for a lack of any of the furious "excitements" of former years, which lured thousands of miners away from steady work, paying claims, and comfortable cabins, to travel in search of a new El Dorado. The nearest approach to anything of this kind we have had has been the "Panama excitement" but this was a very mild form of the disease compared with previous epidemics. Moreover, Panama, was comparatively "get-at-able," and not such a distance from ordinary mining centers as Fraser River, Stickeen, etc.

We have had few mining accidents of large proportions; that of the fire in the Belcher air shaft on the Comstock, by which several lives were lost being the most important. We have been compelled, however, to chronicle from week to week during the year, many accidents by which precious lives were lost. These casualties seem to increase from year to year, which is attributable to the fact that more men are engaged in deep mining than formerly. A noticeable feature has been also that very few mills or reduction works have been destroyed by fire. This class of property is considered by insurance companies to be as risky as any with which they have to do, and insurance is no small item to the mill man. Of late years, however, where large, costly and permanent mills are erected, reservoirs are dug, pipes laid, hydrants put up and every possible precaution is taken to prevent the destruction of the property by fire.

Another fact indicating the faith of capitalists in mining investments and proving that as a business, mining is gaining strength among us, is that the mills now made are larger than ever, the hoisting and pumping gear heavier and stronger, and the buildings and surface works are built in a manner indicating that the owners intend to work properly. The developments in some of the deep mines on the coast have induced mining men to go deeper with a surer hope of success. We no longer scratch over the surface and consider a mine worked out with a 200 ft shaft. In Nevada they have shafts over 2,000 feet deep and are putting up machinery to work 4,000 feet. It was at one time supposed that by the regular increase of temperature with depth, mining below 2,000 feet would be almost impossible and so expensive as to be impracticable. Practice has proved that this idea is fallacious and by various means the heat in the lower levels is decreased and the miners made more comfortable.

We are unable to chronicle this year any very marked improvement in the processes or machinery in use, but are gratified to know that millmen and miners show more care in working ores than they used to and that they manifest great interest in anything calculated to reduce expenses. Machinery is a great deal heavier and more costly than ever. The foundrymen of this city have reaped a harvest from the miners of late, and nearly all the foundries here are kept busy with this class of work. Where formerly a 20-stamp was considered a large order, 40, 60 and 80-stamp

mills are now ordered. The Consolidated Virginia 80-stamp mill started up on the first of January and another mill of the same size will shortly go up alongside of it. On the Summer mine in Kern county an 80-stamp mill is being erected to run by water power and many other large mills in different parts of the State have been erected during 1874.

There is no way for us to make any calculation of the number of men employed in mining on this coast; nor can we tell whether there were more in 1874 than in 1873. The supposition is, however, that there was an increase this year, as so many new mines were opened.

It gives us satisfaction to know that last year capital was much readier to invest in good mines than has been the case for some time. California mines have been to some extent neglected, however, as the capitalists were more interested in Nevada. English capital which flowed into Utah last year so abundantly has been turned to some extent toward this State and some considerable amounts invested in gravel mining property. Our miners complain, however, that good property which will pay three per cent. per month goes begging in this market unless in the shape of stock. The late stock excitements have interested many in mining matters, who may continue to look favorably on them as a means of investment.

There have been no drawbacks to our mining property save alone the high price of quicksilver, which is spoken of at length further on. Tailings mills and works have in some instances shut down and the price of this metal has had an injurious effect. This matter of rich tailings is now receiving considerable attention and they are now in many cases carefully saved. Nevertheless, large quantities of tailings run to waste in the rivers and cañons. With cheap power and quicksilver considerable money can be made in working them over.

Before speaking in detail of this State and its prospects it may be well to give some general remarks on the

Bullion Product of 1874.

Which is considerably higher than that of 1873. The figures given further on ought to open the eyes of the most thoughtless man to the importance of the mining interests of the Pacific Coast. If we could get at the exact number of men employed in each calling we are confident that the miners would make a better showing per capita than the farmers, in the respective States and Territories. The miners of this coast have this year produced according to the most reliable figures obtainable, over 74,000,000 of dollars. And this has been done without any political machinery, without any class organizations, without the passage of any "Resolutions" on any subject and with very little stir about the matter at all. They have been hard at work at their legitimate business and have turned out the useful coin for the commercial purposes of the world in abundant measure.

Mr. Valentine, General Superintendent of Wells, Fargo & Co., publishes the following statement showing the amount of precious metals produced in States and Territories west of the Missouri River during 1874:

The total bullion product of the Pacific States and Territories for the year 1873 was \$72,258,693. This year it was \$74,401,055 showing an increase of \$2,142,362 over 1873. Jno. J. Valentine, General Superintendent of Wells, Fargo & Co.'s Express, who computes the most reliable statistics on this point writes as follows:

We hand you herewith a copy of our annual statement of precious metals produced in the States and Territories west of the Missouri River, including British Columbia, during 1874, which shows an aggregate yield of \$74,401,055, being an excess of \$2,142,362 over 1873. California, Nevada, Utah, Colorado and British Columbia increased; Oregon, Washington, Idaho, Montana, Arizona and Mexico (west coast) decreased. The increase in Nevada and Colorado is merely nominal, but in California and Utah it is \$3,100,000, three-fourths of which is to the credit of California.

1898.	260,000,000	1898.	270,000,000	1898.	270,000,000	1898.	270,000,000	1898.	270,000,000	1898.	270,000,000
1899.	270,000,000	1899.	280,000,000	1899.	280,000,000	1899.	280,000,000	1899.	280,000,000	1899.	280,000,000
1900.	280,000,000	1900.	290,000,000	1900.	290,000,000	1900.	290,000,000	1900.	290,000,000	1900.	290,000,000

In our statement for 1873 we referred to the yield—\$72,258,693—as "undoubtedly the lar-

gest, for one year, in the history of the coast." The accuracy of the statement has been questioned, and the yield of 1853 referred to as being greater. Dr. Lindernum, Director of the U. S. Mint, whose information is probably as reliable as may be had, names \$65,000,000 as the amount produced in 1853, and that amount was not exceeded until 1873, which is now exceeded by 1874, and the recent developments on the Comstock lode justify the belief that the total product for 1875 will approximate \$80,000,000.

We append to this a comparative table, showing the bullion yield for the past three years as follows:

	1872.	1873.	1874.
California.....	\$19,049,038.24	\$18,062,928	\$20,300,531
Nevada.....	25,648,401.09	35,254,507	25,452,233
Oregon.....	1,905,584.92	1,376,389	609,070
Washington.....	226,051.06	209,395	155,535
Idaho.....	2,514,089.78	2,343,664	1,880,004
Montana.....	4,442,134.90	3,889,800	3,439,498
Utah.....	3,521,020.09	4,406,387	5,911,278
Arizona.....	143,770.00	47,788	26,058
Colorado.....	3,001,750.85	4,083,268	4,191,405
Mexico (W Coast).....	535,071.80	888,708	798,678
British Columbia.....	1,350,074	1,250,035	1,636,557
Total.....	\$62,376,914	72,258,693	74,401,055

This makes a total bullion product for three years, including the west coast of Mexico and British Columbia, which do not properly belong in the table, of \$208,896,762. This is a very good showing, and is one to be proud of.

The receipts of treasure in this city for 1874 is given as follows by Mr. Valentine:

1874	Silver Bullion.	Gold Bullion.	Coin.
January.....	\$ 959,962	\$583,195	\$820,437
February.....	1,099,461	630,424	714,944
March.....	1,805,863	610,250	670,662
April.....	1,363,418	807,830	729,246
May.....	1,971,458	949,139	907,077
June.....	1,973,575	856,856	1,320,472
July.....	1,464,179	916,163	1,025,573
August.....	1,495,898	918,082	934,118
September.....	1,654,367	790,978	1,087,613
October.....	1,627,388	767,147	1,222,115
November.....	1,573,972	629,034	1,049,395
December.....	1,118,917	543,133	1,202,276
Total.....	\$18,905,448	\$8,897,471	\$11,633,979
In 1873.....	12,177,598	10,052,123	9,515,385
In 1872.....	12,777,598	10,052,123	9,515,385

There has been less gold and more silver. The sources of the receipts last year are annexed:

From northern and southern mines.....	\$34,621,330
From northern coast route.....	2,206,232
From southern coast route.....	501,437
From Mexico.....	2,007,599
Total.....	\$39,436,588

In 1873..... 31,855,208
In 1872..... 33,842,737

We append a table showing the total gold and silver production of this coast since California was first settled by the Americans. The figures are such as to astonish those who have no idea of the amount of mining done here. About 20 per cent. is added to Wells, Fargo & Co.'s figures to cover bullion conveyed by other means.

Total Gold and Silver Production.

Year.	Gold.	Silver.	Total.
1848.....	\$5,000,000	\$5,000,000
1849.....	23,000,000	23,000,000
1850.....	59,000,000	59,000,000
1851.....	60,000,000	60,000,000
1852.....	50,000,000	50,0

\$22,075,400 in 1873, an increase of \$5,245,500. Of the coinage last year, \$24,460,000 was in gold, and \$2,867,000 was in silver. During the same time the mint at Carson coined \$2,620,775 in gold, and \$1,411,781 in silver, making a total for both mints of \$3,412,265.

The operations of the San Francisco assaying and refining works were as follows for 1874:

Months.	Ounces.	Value.
January.....	66,754.65	\$1,368,442.97
February.....	84,914.50	1,761,610.70
March.....	86,493.24	1,779,861.90
April.....	85,161.68	1,745,840.03
May.....	25,926.40	526,038.10
June.....	129,329.93	2,596,790.65
July.....	127,369.29	2,598,863.95
August.....	130,828.19	2,681,257.48
September.....	119,964.59	2,444,163.55
October.....	108,885.28	2,170,051.15
November.....	94,130.47	1,915,888.39
December.....	95,480.06	1,915,359.66

Totals.....1,137,726.28 \$22,724,108.52

It is but just to say in connection with the table of hullion product given above, that figures they are compiled with care by Mr. Valentine, and are approximately correct. Nevertheless, they should be much larger from the nature of things. These figures represent the bullion, gold-dust, etc., which passes through the hands of Wells, Fargo & Co. as common carriers. Fully 20 per cent. should be added, however, for the sum which passes from the mines by private hands, and other modes of conveyances than Wells, Fargo, & Co. This being the case, if we deduct Mexico and British Columbia from the aggregate, it will still be much larger than is shown in the above table.

The next important question is that of Mining Dividends. As it has an intimate connection, of course, with the bullion product. We give a comparative table showing the dividends from mining companies called on the Stock Boards in this city:

	1872.	1873.	1874.
Belcher.....	\$2,184,000	\$6,762,000	\$5,304,000
Black Bear.....	45,000	69,000
Crown Point.....	1,860,000	5,100,000	3,400,000
Cons. Virginia.....	2,592,000
Cons. Amador.....	50,000
Cedarburg.....	36,000	24,000
Chollar.....	56,000
Charlot Mill.....	51,000
Eureka Cons.....	40,000	300,000
Eureka Cons.....	200,000	125,000
Golden.....	85,000
K. K. Cons.....	30,000	62,500
La Grange.....	12,500
Meadow Valley.....	360,000	180,000
Monitor Belmont.....	75,000
Minnesota.....	60,000
Mahogany.....	15,000
North Star.....	27,000
Pioche.....
Providence.....	3,100
Raymond & Ely.....	2,070,000	300,000
Redington Quick.....	264,000
Yule Gravel.....	10,000

\$6,730,100 \$13,366,000 \$11,805,000

In summing up the above only those mines are taken into account which advertise their dividends in this city. All the above mentioned are on the lists of the Stock Boards, except the Redington Quicksilver, Minnesota and the Black Bear. A falling off is shown in the dividends this year, which is principally due to the decrease of the dividends of the Belcher and Crown Point. It will be noticed by even the casual observer that not one gravel mine is represented in the figures of dividends for this year. This fact alone goes to show how unsatisfactory it is to have any calculation on the dividend list published. Of the hundreds of private corporations mining profitably, not one is mentioned. Some of these mines, like the Idaho at Grass Valley, are what is known as "close corporations," the stock being held in few hands and the mines worked as mines and not as a stock jobbing operations.

We can mention the following prominent California mines, only one of which is on the Stock Board which have yielded \$2,996,503 from 187,391 tons of ore, this year, making nearly \$300,000 each on the average, yet no mention is made of them in the dividend lists published. They are as follows: Idaho, Eureka, Black Bear Plumas-Eureka, Sierra Buttes, Sumner, Hite's mine, Keystone, Empire. We shall speak more in detail of these mines further on. The following table gives an account of all the dividends disbursed by the different mines called in the Stock Board from its organization, up to January 1, 1875:

Belcher.....	\$14,135,000
Crown Point.....	1,368,000
Cons. Virginia.....	2,592,000
Chollar.....	3,080,000
Confidence.....	78,000
Charlot Mill.....	51,000

It is only worth while to mention a few of the mines which have paid and are not included in this list. The Idaho, at Grass Valley, paid in dividends the last fiscal year the sum of \$317,750. Since this mine began running, in 1869, it has paid 517 per cent on the capital stock, or a sum total of \$1,602,700 in dividends. It paid \$102.50 per share last year. The Bald Mountain, from July 1, 1872, to July 1, 1874, paid \$164,000 in dividends. The Spring Valley mine, Butte county, turned out in the year ending last July, \$476,112, of which the owners received \$150,000. The Black Diamond coal company paid this year \$275,000 in dividends, and the Eastport Coos Bay Coal mining company paid \$12,500. Many of the quicksilver mines are paying well, and almost all the

hydraulic mines which are in operation are paying. None of these, however, are called in the Board, and their names do not therefore appear. Many other quartz mines are in the same category. But even taking those called in the Board, in the list given above, by comparing the total assessments and the total dividends, we see a profit to the stockholders of the large sum of \$25,212,569, showing an immense gain on the capital invested. We have said enough on this subject to inform the reader that while the richest mines are represented in the tables given, it is not practicable to gather the same information from close corporations.

Ditches and Gravel Mines.

It is impossible, within the limits of a newspaper article, to give more than a brief review of the operations in the different States. We shall therefore confine ourselves entirely to California; and even then can only mention in general terms the results of the year. The statistics of hullion production give us an increase over the year 1873 of \$2,247,709. This is mainly due to the fact that last year was a much better one, from a miner's point of view than the previous. The water supply was large, and consequently more washing could be done. Many new hydraulic mines have been opened this year, and many more are shortly to be opened. Several important mining ditches were dug in 1874, which will open new tracts of country, and furnish a more abundant supply for old mines. Prominent among these was the Amador Canal, as it is called. This will be of inestimable advantage to Amador county, and already many new mines are being opened that will last for years to come. Heavy gravel mining will in future be a feature in the county, and will add largely to the wealth of the community. The canal will not only furnish water for the gravel mines, but will furnish power to the quartz mines. It has a capacity of 5,000 miner's inches of water, and the water can be so utilized as to make a single head serve many purposes. When used for mills, it can be used for placer mining, and thence to the plains for irrigation. An immense reservoir is being built for this canal at New York Ranch, which shall cover 140 acres of ground and hold 800,000,000 gallons of water. The head of this reservoir is of granite formation. The canal is 45 miles long, and is built with great strength and care.

The big ditch of the North Fork company, built particularly to work the mines near the North Fork of the Feather river, about six miles south of Big Meadows, in Plumas county, was finished last month. This was also a difficult undertaking. This ditch is 25½ miles long, and there are eight miles of pipe in addition to reach the company's property. Considerable tunnel work was done in building this ditch, which is six feet wide on top and three feet deep. It furnishes water for a large extent of country, and the result of the undertaking will be shown in the bullion product next year.

The El Dorado Water and Deep Gravel mining company's canal is also an undertaking worthy of mention. They have had sometimes as high as 1,200 men at work in this ditch during the season. The capacity of the canal is 12,000 inches for 24 hours, and as the company can only use 3,000 inches they can sell to miners on the route some 7,000 inches, allowing for evaporation and leakage. The canal is big enough to float lumber nearly to Placerville. Some 5,000 inches will run through this season, but the whole work will not be done until the next season. It will furnish water for many mines in the gulches and flats which have been short before this.

The Maxwell ditch, in Plumas county, which was commenced in 1872, will probably be extended down the river as fast as necessary to work the numberless bars and gravel beds under the ditch line. The ditch carries 2,000 inches of water, with one of the best water privileges in the county.

At Cherokee Flat, Butte county, some of the largest hydraulic operations in the State are going on. The Spring Valley company, at that place, have expended in works, flumes, ditches, reservoirs and water privileges, over one million dollars. They have four miles of pipe on the line of their ditch, and ten miles of sluices, varying from four to six feet in depth; they have also twenty-three undercurrents. They employ about 160 men, and for the year ending July, 1874, shipped \$476,112. The two ditches owned by the company are 60 miles in length, six feet wide on the bottom and eight feet wide on top. They are four feet deep and run a stream of 2,200 inches of water. This mine proposes to send a bar of gold worth \$100,000 to the Centennial Exposition.

Another big ditch run this year was that of the Milton Water and Ditch Co., in Nevada county. This company purchased this year extensive water rights and storage reservoirs in the middle Yuba river. Their ditch holds 2,500 inches of water. The North Bloomfield Gravel Co., at the same place, last year constructed extensive works for the improvement of their property. They completed their large tunnel last month. It has taken about two and one-half years time and the expense has been enormous. It will pay for itself soon, however. This tunnel is nine thousand feet long. These mines are on the San Juan range, in which are located several important gravel districts, such as Birch Corral, Empire Flat, Kate Hayes Flat, Birchville, Buckeye Hill, Sweetland, Manzanita Hill, San Juan, Badger Hill, Cherokee, Chimney Hill, Columbia Hill, Kenneho Hill, Grizzly Hill, Lake

City, Malakoff, Hombug, Relief Hill, Wolsey, Moore's Flat and Snow Point, all old camps on the gravel channel.

Around Dotch Flat and Gold Run extensive hydraulic operations are going on. The Gold Run Ditch and Mining Co. bring water from Bear and South Yuba rivers, through 23 miles of ditches, and use some 2,000 inches of water on their claims. They are running a 3,000-ft. tunnel to get the necessary fall to work certain claims, a 1,000-ft. branch tunnel from it is finished. The Cedar Creek, an English company, who bought the Placer county ditch, now own 60 miles of ditch. The main ditch gives them 6,000 inches of water. This company now owns 32 claims, or 200 acres of mining ground, and sells about 1,500 inches of water to outside parties. They are running an 8x8 tunnel 3,000 feet long. The South Yuba Canal Co., at this place, is also selling to miners about 3,000 inches, which is brought through 28 miles of ditch from the South Yuba. In this vicinity everything is flourishing. The Indiana Hill Co. are running a tunnel 2,200 feet long, and they will begin washing in February.

Calaveras county now rivals the more northern counties in hydraulic mining. New locations are constantly being made, and various tunnel and hydraulic operations are vigorously prosecuted. The mines are of a permanent character, and the result of the present season's work will be a good one. Some of the mines now worked were a few years since considered as exhausted diggings.

The improvements recently made in hydraulic mining and the reduced price of water in many places consequent on competition, have increased the value of mining property in many places. Though hydraulic mining has been carried on for nearly twenty years, at many points it was only recently that steps were taken to develop the deep gravel deposits, all the work having been done at easily accessible points. The value of a hydraulic mine depends greatly on the facilities for working it, and each year new mines are opened up by ditches and flumes.

Drift Mining.

Drift mining has of late years become quite profitable in California. The term drifting, as applied to this class of operations, relates to the mode of extracting the auriferous gravel by means of tunnels and gangways, or galleries, and washing the dirt in sluices. This system is rendered necessary on account of the capping of volcanic matter overlying the ancient channels and rendering hydraulic operations impossible. In hydraulic mining the entire face of the bank is removed by the pipe; in drifting claims only the lower stratum of gravel lying on the bedrock is mined and washed. The average depth of pay gravel, when mined in this manner is three feet. Careful estimates place the yield of gravel generally at \$1 per car-load of 16 cubic feet to be considered profitable for drift mining, and the minimum yield is fixed at from 85 cents to \$1 per cubic yard of broken ground—not ground in place. The old Live Yankee claim in Sierra county now nearly worked out, yielded during active operations (from 1855 to 1863, inclusive), the sum of \$698,534, of which \$370,100 was used for opening up the claim, and the dividends disbursed were \$328,368. For several years after, and until the ultimate exhaustion of the ground, the dividends averaged \$10,000 per annum. The claim yielded from date of opening \$1,000,000, of which half was paid in dividends. The Bald Mountain claim now being worked in Sierra county, may be taken as a specimen of this class of claims. We gave a detailed description of this claim a short time since, so it is only necessary to refer to it here incidentally, with respect to the profit of this class of claims. This company paid out \$200,000 in dividends between April, 1872, and January 1st, 1873, the only outlet being \$20,000 for running their tunnel 1,800 feet long. The total yield from July 1st, 1872, to July 1st, 1874, was \$328,352, of which \$164,000 was paid out in dividends. The ground has paid them \$2.76 per car-load, or over \$1.09 per cubic yard. The percentage of dividends to gross amount is 50 per cent. Up to last October they had taken out \$345,079 from a piece of ground 1,000 feet long by 500 wide, exclusive of the unworked ground within the area, and not including the gravel piles in the company's yards. These figures and those given below give an idea of the relative profit of this kind of mining, which is very little understood outside the mining districts even in California.

The Indiana Hill Blue Gravel Co., or Cement Mill Co., as it is sometimes called, at Gold Run, is also a drift claim. They crush the gravel with an 8-stamp mill. They work a breast seven feet high and 100 feet wide. The mill crushes 45 car-loads in 24 hours, each car-load weighing 1,600 pounds. The company has been running a long time. We give from a reliable source the result of the last three years' work. In 1874, with nine months run, they crushed 10,017 car-loads, which yielded \$30,811.50, an average of a little over \$3 per car-load. In 1873, with seven months run, 6,600 car-loads yielded \$24,000, or an average of nearly \$4. In 1872, with four and a half months run, they crushed 3,300 car-loads, which yielded \$19,410, an average of a little over \$5 per car-load.

The placer mines near Oroville, in the "Lava Beds," have been purchased this year by Chinamen, who have been working them with profit. Upwards of 4,000 Chinamen are at

A Chapter of Tule History—Staten Island.

[From Pacific Rural Press.]

EDITORS PRESS:—The season of 1873-4 is completed and its lessons of success or failure are ready for our instruction. There are many tasks and many learners in this school, and each learner has his own task. The present theme is a chapter from the experience of the tule lands of our State. The swamp lands generally, of California, have been growing in favor within the past few years, and all information on the subject excites attention. Unfortunately for the very object aimed at in recent publications exceptional facts and circumstances are insisted upon too much as if of common occurrence. It must be noticed, as prefatory to every remark, that experiment has not yet given sufficient data from which to deduce a certain rule. Our chief concern still is to gather and compare data, and such is the purpose of the writer of this article. The remarks are also intended to be confined to one district of swamp land and will detail briefly the history of that district.

Staten Island.

The tract in question is formed by the forks of the Mokelumne river just before that river unites with the San Joaquin, and is also within easy reach of Sacramento river, either across a narrow neck of land, or farther by means of the many streams that link this well-watered region. It lies in Sacramento county, and from Walnut Grove Post-office, which is one mile from the head of the island, a good road extends 30 miles through a thickly-settled and fruit-bearing country to Sacramento city. Like all other fresh water tule lands, Staten island, in its natural condition, was a swamp over which the higher tides flowed, keeping it continually wet. As would be expected, the banks of these lands are usually somewhat higher than the interior, and the water flowing in at a spring tide is kept within, as in a basin, so that there are usually several inches of water always on the land back from the shore. In very dry seasons, however, the lowness of the river lessens the frequency of the tidal overflow, and this, with the large evaporation, renders the land dry enough for pasturing stock. At such times in the past, large herds of cattle and bands of sheep have been pastured on the tule lands, without any reclamation or leveeing whatever, and considerable quantities of the wild grass have been cut and baled under like circumstances. This grass has a bayonet-shaped blade and grows from a strong root and stock, branching out a few inches from the ground. It prefers a soil composed almost entirely of vegetation, in which it thrives luxuriantly, attaining a height of four or five feet. Wherever the quantity of sediment increases in the soil, the tule, a tall, round rush, often ten feet high, becomes more common. It is this plant, said to be so termed by the Indians, that gives name to the lands under consideration. The first settlement on the tule lands were made along the Sacramento river and for a long time were confined to the high ridge of bank land formed by the sediment which had accumulated from the winter floods. This bank land has been and still is very valuable as orchard and garden land. The settlers in time discovered that the back land was good for pasture and also that the soil was chiefly of vegetable formation—in many cases a fair quality of peat—and that when dried it would burn in the ground. They also found that any crops planted in the ashes of the burnt land would grow and yield remarkably well. In this way, the value of the tule lands was demonstrated upon a small scale, and capitalists, thus assured, have undertaken the problem upon a large scale, and one phase of that problem is here presented in this account of Staten island.

The Work of Reclamation

Was begun in June, 1872. Eight dams were put in as many sloughs, without the aid of piling, except in the instance of the largest slough, which also was the first dam built. Had it been left to the last it could likely have been completed without piling. The great difficulty in the way of building dams, and levees, too, on the tule lands is the lightness of the earth. In many cases the sods cut from the ground float. Such material should be avoided entirely and heavier sought. This can always be found in the vicinity of the sloughs, and, with the judicious use of light brush, a substantial bond can be made.

The largest portion of the leveeing was done by a steam dredge in charge of W. C. Sullivan. This machine digs a ditch twelve feet wide and four and one half feet deep, somewhat after the Osgood plan, except that the bucket is attached to a movable frame on a turn-table, which turns to the right or left to dump the earth. The whole apparatus is operated on a scow which floats in the ditch it digs, and is drawn up to its work by means of a capstan and anchor ahead. It was claimed for the machine that the large mass of a full bucket, about one cubic yard, dropped six or eight feet while soft, would make a more compact levee than the small sods cut out, handled and laid in the levee by Chinamen. The experience of the past winter seems to confirm this claim. The machine

levee was indeed broken in a number of places; but the embankments were small, and in no case was the earth carried away. The expense of excavation is also less than by Chinamen; but unfortunately the machine cannot change the depth and width of its ditch, nor vary its cast of the earth, and hence, being confined to a uniform ditch, the field of its operations is very limited. It is a matter of great regret that steam dredging apparatus has not been employed to a greater extent. Both on Staten island and on other tracts of tule land large mud flats have been formed by sedimentary deposits brought down by the winter rains, and this material can be put into levees at a reasonable cost by steam dredges. But the cost of it double or treble that of the peaty soil of which Chinamen build levees, still it would be cheaper than the peat. It has required the loss of several large crops and the overflow of valuable lands to teach the reclaimers of tule lands the absurdity of erecting barriers against water of material that might float.

The first step toward proper reclamation was in the use of the earth taken from the river bank on the outside of the levee. There the sediment already spoken of had accumulated to the depth of 18 inches, though considerably mingled with the roots of vegetation, and the sediment and roots combined make a very substantial levee. This method was first tried on Staten island, in the spring of the year just passed, in the face of many prophecies of evil results, founded mainly on the bad effects of cutting ditches on the outside of the levee on Sherman island. On that island breaks in the levee and serious cracks in the soil under it have occurred, but the experiment on Staten island has been eminently satisfactory, and the example there set is being followed on other similar tracts. The earth taken from the outside of the levee is a yellow loamy clay, and the embankment built of it was found, after six months' usage, to have shrunk and settled very little compared with the previous levee of peat, and a large percentage of what loss did occur was, doubtless, owing to the foundation upon which the addition was built. Nor was there any break in the levee after the exterior soil was added, although the levee was subjected to the tides of June, the largest of the year. After this satisfactory showing it remains now but to take one step further, and with a steam dredge get a material entirely free from vegetable matter, and furnished in unlimited quantities on the margin of the land to be reclaimed, and with it erect on an unbroken sod, effectual walls against the inroads of floods.

Cultivation.

The problem of the tule lands now turns wholly upon their reclamation, and involves mainly the substance of which the levees are built. There is no longer any question regarding their productiveness. All who know these lands are satisfied in this respect. Even those who have been disheartened by the loss of their crops bring no charge against the soil, but commend it saying: "The land is good enough if you only keep the water off." The soil is composed mainly of roots and decayed tules, grass and other plants, and consequently is generally nothing but a peat bed, varying in depth from 5 to 30 feet. The surface kept dry in the summer will burn in the fall to the depth of several inches, and in the ashes of the sod the crops are planted. In the fall of 1873 Staten island was fired, but owing to the short time the levee had been completed the burning was not extensive. Planting was begun by the three or four settlers in January, 1874. Wheat was first sown until about the 1st of March; after that common and chevalier barley were sown until the 15th of May. Most of the crops were put in with sheep, which were driven compactly over the burnt land after the seed had been sown. The remainder were harrowed in. The planting of the crop was found to be comparatively light work whether with sheep or harrow, and at a cost of from \$2 to \$4 per acre, including the seed. The chief trouble was from the miring of the horses. Various appliances in the way of horseshoes were resorted to, the best of which was an iron shoe with an exterior ring attached to it so as to receive the horse's weight. With such a "tule shoe" teams could get over the ground with considerable ease.

Harvest.

Seed-time being past, harvest began to be looked for. The grain sprouted and looked well; The heads appeared and nodded in the wind and gladdened the eye of the farmer. Then, when the fields were whitening for the harvest, a serious evil threatened in the shape of red rust. The wheat and barley were both affected; but it was noticed that the late sown grain suffered most. Wheat sown previous to the first of February escaped almost entirely without injury, and the later sown resisted the rust much better than was expected when it first appeared. It was thought also that the continued wet weather and late high water had as much to do in causing the rust as the late sowing. Early sowing, however, seems to be successful in any condition of weather, and a remedy in case of a very wet season. When harvest came, crops of undoubtedly large yield stood ready to be gathered. Good judges estimated the yield from 40 to 80 bushels per acre. Actual experiment found samples that produced, one, 77½ bushels per acre; another, 58½ bushels per acre, both of wheat. Elated by these large figures, the farmers, inexperienced on tule soil, declined contracts which they thought too high, and undertook the work of harvesting themselves. On account of the softness of the ground it was thought that

headers would be too heavy, and reapers were employed instead to cut the grain. In most cases the grain lay on the ground for several weeks after it was cut, and was at length loaded, loose, into wagons by Chinamen and hauled either to the attack or to the threshing-machine. The tires of the wagons were two and one half inches wide, and the ease with which they, and also the reapers got over the soil was quite conclusive that headers might have been used, and thus saved the large expense of so much handling of the grain in the field. A large portion of the crops was not harvested till long after they were ripe, and, in consequence, the grain fell down so that the reapers could not cut cleanly, but left on the ground as much as one-fourth to one-half of the crop. Headers with their lifters would have prevented this serious loss.

The Yield.

Notwithstanding the defective harvesting, the yield was very good. The land was cultivated in scattered tracts, and no exact measurements could be readily made; but, estimated by the quantity of seed sown, there were about 1,000 acres—450 in wheat and 550 in barley. The figures taken from the threshers' accounts show, in the aggregate, a yield of 5,800 sacks of wheat and 8,400 sacks of barley. The average yield per acre was, consequently, thirteen sacks of wheat and fifteen sacks of barley or, by measurement, twenty-nine bushels of wheat and thirty-four bushels of barley. While these figures show a good yield, they do not show the entire production of the crops. In addition to what was left on the ground, one large stack of wheat was burned up and a very considerable quantity of barley was destroyed by the early rain which overtook the late threshing. It is very safe, therefore, to say, that one-fourth of the crop was lost, and the true average yield would be represented by thirty-nine bushels of wheat and forty-five bushels of barley per acre. A crop of wheat cut for hay yielded about three tons per acre. A number of acres of Indian corn were planted, but not being cultivated after the planting nothing came of it but promises of an abundant yield in case of a proper cultivation.

The Coming Season.

Such is the issue of the first year's crop on Staten Island. While it did not fulfill the sanguine expectations of the farmers, still the result is quite satisfactory. The defects and losses were due mainly to inexperience on new ground, and were no more than what should have been expected in an untried field. Indeed it is a matter of surprise that the outcome was as fortunate as it was. But now, since experience has been gained, another year will see better cultivation, better harvesting, and a far better yield. A larger force, with vastly increased facilities, undertake the coming crop. Ten farmers are already busily engaged upon the island, and they will cultivate not less than 4,000 acres, mostly in wheat and barley. Excellent dwellings and very substantial barns, just completed, add largely to the comfort of the residents and change the spacious area into a well-settled neighborhood. The levee is being enlarged, notwithstanding the successful resistance to the severe test of last winter's waters, as it is the determination of the settlers to make "assurance doubly sure." December has passed without rain, and a prosperous season is confidently expected. Should these reasonable expectations be fulfilled, the tule lands will, during the coming season, take a great stride toward that high position they are destined to hold among the richest agricultural districts of our favored State.

L. C. MOFFEE, Engineer.

Staten Island, December 31, 1874.

MINING ACCIDENT.—Workmen were engaged in stoping at the California mine, on Tuesday night, when, without warning, they struck through into the old Illinois works, and were instantly flooded with the water which was penned up in those works. The men all rushed to get through the tunnel and succeeded in doing so without injury, except Mr. Herrihausen, who escaped with some severe injuries about the head and shoulders. The tools, cars, etc., which were used by the employees were left in the stopes, and are probably covered up with the sediment and other debris from the old works. The accident resulted very fortunately. It is a wonder that every man was not drowned or bruised to death by the rushing torrent of water which was let loose by breaking the wall separating the works.—*Nevada Transcript.*

ARIZONA MINES.—The Arizona Citizen says: At no time in the history of Pima county, has mining operations been so numerous and full of encouragement. We have an article prepared showing in detail many facts, but it goes over for the present.

In Yavapai, the condition is much the same. Within a few days Mr. C. P. Crawford has applied for survey for patents to six copper mines Eugene E. Burlingame for two, and C. M. Shannon and B. M. Hughes for one, in Yavapai county at Clifton, and very soon we are told applications for survey of about 10 more will be made.

The Stockton Woolen Mills, says the Independent, constitute one of the best managed and most useful industries in Stockton. Forty thousand dollars is invested in the business. There are 25 employees, to whom \$1,000 wages is paid per month. During 1874 the mill consumed 20,000 pounds of wool. The manufactured goods during the same period consisted of 75,000 yards of flannel and 7,500 pairs of blankets. Total value of manufactures, \$75,000.

BALL'S
SWEEPING DREDGE,
A NEW AND VALUABLE
CALIFORNIA INVENTION,
Has been very lately well proven by per-
forming a job of dredging at the mouth of
San Antonio Creek, at Oakland, Cal.

There is but this one machine that has ever had these improvements employed. It is an old machine, formerly built for another device, and is unfavorably constructed for Ball's improvements; yet this first temporary experimental machine has filled a scow of eighty-five cubic yards in sixteen minutes in unfavorable digging. For durability, digging hard material and fast work, it has a reputation (supported by leading engineers) as having no equal.

Testimonials and references will be given on application to the inventor, who is the sole owner of patents (excepting having made an assignment of the one machine now belonging to the Central Pacific Railroad Company) Having resolved not to sell any rights unless upon a basis of actual work performed by a machine built by myself for the purpose of fairly establishing the worth of the invention, I therefore offer to sell machines or rights on the following plan, which is warranting the capacity of the machine by actual work:

I will enter into an agreement with any responsible party to build and sell a machine, scows and tender, all complete, and right of all my improvements in dredging machines throughout the Pacific Coast for \$20,000, warranting the machine to dredge six cubic yards per minute (to fill a scow at that rate). \$20,000 will but little more than pay the cost of building the machine, scows, etc., all complete; therefore I am proposing to ask nothing for my patents unless my machine dredges more than six cubic yards per minute. But it shall be further agreed that in case (at a fair trial to be made within a stated time) the machine shall fill a scow at the rate of more than six cubic yards per minute, then \$10,000 shall be added to the price above stated for each and every such additional cubic yard thus dredged per minute, and for additional fractions of a cubic yard thus dredged in the same ratio the \$10,000 is to be added to said price above stated.

I will sell any other Territorial or State rights (either United States or Foreign) upon the same plan and at a lower price proportionately than the rights for the Pacific Coast.

I will sell a single machine with scows and all complete, and right to use the same in a limited territory, for \$20,000 on the same plan as above stated, but will add only \$2,000 to each additional yard over the six cubic yards per minute. Each machine is not to employ more than two 10x20 inch engines.

Payments to be made in U. S. gold coin on delivery of machine, as may be indicated by agreement.

Address,
JOHN A. BALL,

N. Seibert's Eureka Lubricators.

THE HIGHEST PREMIUM
Awarded by the Mechanics' Institute Fair, San Francisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers to be superior to any they have ever used; feed constantly by pressure of condensed water, supplied by pipe A, regulated under the oil by valve J, and forced out through check valve and pipe B into the steam pipe C; it then becomes greasy steam, passes to all the valves and cylinder at every stroke of the engine; glass tube I indicates amount used per hour. Packing on rods and stems lasts longer, and the rings on the piston will not corrode. One pint of oil will last from three to six days, according to speed and size of engine; I, sliding gauge; K, valve to shut off when engine stops; H, F, valves to shut off in case of frost; steam does not enter the cup; it is always cool; warranted to give satisfaction. Patented February 14, 1871. Made by California Brass Works, 125 First street, S. F. 24V23

Averill Chemical Paint,

MANUFACTURED BY THE
Cal. Chemical Paint Co.

PURE WHITE, AND ANY SHADE OR COLOR.

This Paint is prepared in liquid form, READY FOR APPLICATION—requiring no thinner or dryer, and will not spoil by standing any length of time.

It is Cheaper, more durable, more Elastic, and produces a more Beautiful Finish than the best of any other Paint.

It will not Fade, Chalk, Crack, or Peel off, and will last twice as long as any other Paint.

In ordering White, state whether for Outside or Inside use, as we manufacture an Inside White (either Flat or Gloss) for Inside use, which will not turn yellow, and produces a finish equal to the finest China Gloss.

Put up in $\frac{1}{2}$, 1, 2 and 5 gallon packages, and in Barrels. Sold by the Gallon.

For further Information send for Sample Card and Price List, or apply to the manufactory and office,

TO COPPER SMELTERS, BLUE-STONE
& SULPHURIC ACID MANUFACTURERS.

For sale or to lease the LEVIATHAN COPPER MINE, in Alpine county, California.

The ore, which is in the form of silicate, black and red oxide, and gray sulphide, with metallic copper finely disseminated, averages from two to five feet thick, and 15 to 50 per cent. copper. A few parcels taken out during exploratory operations, realized \$30,000 for Bluestone. In eight, 2,000 tons 20 per cent. ore; on dump, 300 tons 15 per cent. Supply inexhaustible. Title perfect. Minimum present capacity, 10 tons per day, which may be extended indefinitely. Cost of extraction, \$2. There is also a stratum of sandstone 20 feet in thickness, impregnated with 26 per cent. pure sulphur. To a coin purchaser highly advantageous terms will be offered. For further particulars apply to Leurs Oshalmers, Silver Mountain, Alpine county, Cal.

Ayer's Hair Vigor

RESTORING GRAY HAIR
TO ITS NATURAL VITALITY AND COLOR.

Advancing years, sickness, care, disappointment, and hereditary predisposition, all turn the hair gray, and either of them incline it to shed prematurely.

AYER'S HAIR VIGOR, by long and extensive use, has proven that it stops the falling of the hair immediately, often renews the growth, and always surely restores its color, when faded or gray. It stimulates the nutritive organs to healthy activity, and preserves both the hair and its beauty. True brassy, weak or sickly hair becomes glossy, pliable and strengthened; lost hair regrows with lively expression; falling hair is checked and established; thin hair thickens; and faded or gray hair resume their original color. Its operation is sure and harmless. It cures dandruff, heals all humors, and keeps the scalp cool, clean and soft—under which conditions, diseases of the scalp are impossible.

As a dressing for ladies' hair, the Vigor is praised for its grateful and agreeable perfume, and valued for the soft luster and richness of tone it imparts.

work in this vicinity. They have plenty of water, and sink small shafts to get out the gravel.

Quartz Mining.

In Amador county reports for the developed quartz mines are encouraging; lodes in course of development giving, as a general thing, good promises of future business. In the county during the year ending in June last, 83,450 tons of ore were crushed. There are 15 quartz mills in this county, and 11 mining districts 296 miles long in the aggregate. There were 2,890 tons of coal mined in this county last year.

Monterey county is one of the counties lately brought into notice as a mining region. New mines have recently been opened there, but no extensive developments have yet been made. Cinnabar and coal are the principal things sought for, and prospectors have for several months been searching for both.

In Inyo county, beside Panamint, elsewhere referred to, the Cerro Gordo mines are working away, turning out base bullion by the ton. There are two furnaces, there each about 30 tons capacity. These furnaces produce each about 12½ tons of bullion per day, which is worth about \$115 in silver and \$90 in lead per ton. The mines in this camp are not half opened, yet they are doing very well. A correspondent of ours a short time since gave us some figures of the yield in which he puts that of 1874 as follows: capital invested in furnaces, mines, bed-rock tunnels, etc., during the year, \$15,000; bullion produced 6,000 tons; net profits at \$80 per ton, \$540,000; total capital invested in the camp, \$100,000; total net profits since 1869 at above estimated, \$1,800,000. This is a very good showing.

Panamint, the seat of the last stamped, is in a mountainous rocky region at an elevation of 7,000 feet. The ore is quartz, containing silver, copper, lead, and a little gold. The ore is rebellious, and is shipped to Liverpool for reduction. It assays all the way from \$100 to \$3,000 per ton. It costs to ship this ore to Liverpool \$55 per ton. The ores contain from 10 to 30 per cent. copper, which assists greatly in paying these freight expenses. There are now about 2,000 men in the camp, a 20-atamp and a 5-atamp mill, a newspaper of diminutive size, and lots of prospective millionaires. The capitalists who have invested there are in earnest, and have gone to work properly to develop the mines. Panamint has yet to prove its claim to be called a "Second Washoe." It is young yet, however, and may begin to pan out in the spring.

We have not space to enumerate any details of the result of quartz mining operations in California. Mines are being worked in all directions, and with varying results of course. It gives us pleasure to record, however, the fact that some attention is being turned to this partly neglected branch of operations in California, as people are beginning to find out that they can make money out of quartz at home as well as in the neighboring States. The California quartz mines are worked at a less cost than those on other parts of the coast. There are hundreds of good mines, however, lying idle, only needing the required capital to become good paying properties. The operations of some heavy capitalists in the Southern counties has given a wonderful impetus to quartz mining in those localities, and if they are successful, it is to be hoped that the example will become contagious. At any rate, it has already had the effect of greatly stimulating prospecting, and several new districts have been found. In the spring, when the weather becomes propitious, the Southern counties will be alive with the overflow of prospectors from Panamint, and new discoveries will be the result.

Results from Ten Leading Mines.

We are able to give, through the courtesy of Mr. Skidmore, who is collating statistics of California for the U. S. Mining Commissioner's report, a brief summary of some of the leading quartz mines of California. These are the Idaho, Nevada County; Eureka, Nevada City; Empire, Nevada county; Black Bear, Siskiyou county; Plumas-Eureka, Plumas county; Sierra Butte, Sierra county; Sumner, Kern county; Hite's mine, Mariposa county, and Keystone, Amador county. There are some fifteen of these mines which have yielded over \$200,000 each. These returns embrace ten of the leading mines, exclusive of the Consolidated Amador and Chert Mill, returns from which have not yet been received. The product of the ten mines above enumerated, was \$2,995,500 in 1874, from 187-391 tons of ore, making an average of nearly \$300,000 each. The average product of the ten mines was \$21.39 per ton. Average cost of milling was \$1.84. Average cost of mining was \$5.70. Average earnings was \$13.85 per ton. Only one of these mines is called in the Stock Board—Eureka—so their yield or dividend is not mentioned in the list of dividends. The cost of milling by steam runs from \$2 to \$2.10 per ton, and the lowest cost of milling by water power was at the Sierra Butte mine—83 cents per ton. All these mines own their own mills. They have an aggregate of 361 stamps, which does not include the 80-stamp mill being built by the Sumner mine, Kern county, which is to be run by water power. The greatest weight of stamp is 900 pounds, at the Empire mill, Grass Valley. The smallest weight of stamp is 500 pounds at the Hite's mine, Mariposa county. The greatest yield per ton from one any of the ten mines, \$40 per ton. The lowest yield per ton was \$13. The miner's wages run from \$2.50 to \$3.50 per day. These

ten mines employ 997 skilled miners, exclusive of the surface and mill men. The highest production from any one of the mines was \$684,811 and the lowest was \$160,000. Strange to say the one which made the lowest product is considered the one which will sell for the most money, and at the same time, the one which produced the highest grade ore gave the smallest total yield. These figures will give, without going into details of the particular mines, a good idea of costs, etc., as the figures are reliable and carefully averaged. The low cost of milling will probably surprise those people who are paying from \$7 to \$15 per ton for crushing at custom mills.

To the Barleigh drill, now so extensively used on this coast, must be given considerable credit for cheapening mining and hurrying up tunnel work. They have been of the greatest assistance, and have very much lessened the cost of large operations, either in sinking, sloping or tunneling.

Change of Mining Centers.

To those who were in this State only a few years ago it may be interesting to note the changes of mining centers which has taken place in California within the past two years. Here are all the coast counties coming into notice as mining regions which were considered "cabbage orchards" by the miners not long since. Many of the counties now look with as much interest on their mineral as on their agricultural products. Napa, Sonoma, Solano, Lake, Mendocino, Alameda, Contra Costa, Monterey, Los Angeles, Santa Barbara, San Diego, Santa Cruz, San Luis Obispo, Colusa, Yolo and Fresno counties, all have mining districts. The coast counties were formerly considered only fit for agricultural purposes, but now there is as much prospecting as plowing done. In Napa, Sonoma, Lake, Colusa, Monterey and San Luis Obispo counties, they are very much excited over the subject of quicksilver, as they are in fact in the other counties mentioned. Coal has been found in some of these counties, as has also silver and gold. But the principal object of search in most of the counties mentioned, is that slippery metal

Quicksilver.

This has become a metal of even more importance than ever of late on account of its scarcity and consequent high price. The quicksilver excitement as well as its price may be said to have kept up to the biggest pitch during the whole year. The value of the metal, the accessibility of the localities where it is found, the broad area of country where it is likely to be met with, and the value of a good mine are all incentives which combine to keep up the excitement. It is confined to no particular locality in the State, and all classes of people have turned prospectors to find it. Honest farmers have dropped the plow and taken to the pick, and even the female part of the population in some places, have obtained prospectors' outfits and scoured the hills in search of the precious metal. It has been selling at \$1.55 per pound for some months past, and is likely to go higher before it falls lower. Our mines must be actively worked to meet the extraordinary demands which the immense mills and heavy mining operations at present conducted require. Only a few of the new mines are yielding quantities of any moment, though many of them are being steadily developed. A great many small claims are being rapidly developed which will in the future add to the production. It is impossible to state the number of quicksilver claims in California, but after some difficulty we have been able to arrange the following list of producing mines, and add to it a list of a number of others which are likely to become good mines when further developed. We give in this list also the number of retorts, and furnaces in use at the producing mines, together with the name of the style of furnace:

Producing Quicksilver Mines in California.

ALMADEN MINE, Santa Clara county. Has six "Almaden" furnaces; building one more. Mr. Randol the Superintendent, informs us that the product of the mine in 1874 was 9,084 flasks.
REDINGTON MINE, Napa county. Has two Knox & Osborne, and two Almaden furnaces running. Building two more Knox & Osborne furnaces. The mine is supposed to yield about 1,000 flasks per month, exceeding the product of the Almaden, and producing more than any other mine in California.
CALIFORNIA BORAX CO.'S MINES, Lake county. Has two Luckhardt furnaces, a Knox & Osborne furnace, a Wallbridge furnace and five large retorts. Will erect another Knox & Osborne furnace in the Spring.
GREAT WESTERN, Lake county. Has one 10-ton Luckhardt furnace; also one known as the Great Western or Green furnace—30 tons.
AMERICAN MINE, Lake county. Has a ten-stamp mill for crushing the ore, 12 retorts, a Luckhardt furnace, a Wallbridge furnace, and a Pirschbacher furnace.
NEW IDRIA MINE, Fresno county. Has two "Almaden" furnaces and a Maxwell furnace.
MONTEREY MINE, near New Idria, has a small Almaden furnace.
GUADALUPE MINE, Santa Clara county. Has two small Almaden furnaces and building a Maxwell furnace.
ENRIQUITA, Santa Clara county. Hoisting ore which is reduced at the Almaden mine.
NORTH ALMADEN, Santa Clara county. Building a "Nestle" furnace.
CERRO BONITO, Fresno county. Has a Knox & Osborne furnace.
CALIFORNIA MINE. On line of Napa and Yolo counties; has a Knox & Osborne furnace.
OCEANO, San Luis Obispo county. Building a Louis Janin furnace.
KEYSTONE, San Luis Obispo county. Just completed a furnace.
BUENA VISTA, San Luis Obispo county. Have a very small Almaden furnace.
SUNDERLAND, San Luis Obispo county. Has a Luckhardt furnace.
MANHATTAN, Napa county. Has a Knox & Osborne furnace.
PRINCE, Napa county. Has a Knox & Osborne furnace.
ATENA, Napa county. Has a Knox & Osborne furnace.
IDA OLATTON & YELLOW JACKET, Napa county. Have a Knox & Osborne furnace between them.

ABBOT MINE, Lake county. Has a Knox & Osborne furnace.
BUCKEYE, Colusa county. Has a Knox & Osborne furnace and retort.
BARTLENAKE, Sonoma county. Has a Luckhardt furnace and retort.
ANNIE DELOHER, Sonoma county. Has a Knox & Osborne furnace, just completed.
GREYSER, Sonoma county. Has a Knox & Osborne furnace just completed.
CLOVERDALE, Sonoma county. Has a Knox & Osborne furnace just completed.
JOSEPHINE, San Luis Obispo county. Small 8-ton furnace.
LIVERMORE, Sonoma county. Has a modified form of the Knox & Osborne furnace.
SONOMA, Sonoma county. Has a Luckhardt furnace.
MOSQUITO, Sonoma county. Has five retorts.
OAKLAND, Sonoma county. Has five retorts.
EXCELSIOR, Sonoma county. Just completed a Winterburn furnace similar to the Green or Great Western.
ST. JOHN, Solano county. Has a Neate furnace.
KEARSARGE MINE, Lake county. Has retorts; but no furnace.
EASONS, Sonoma county. Erecting a Wallbridge furnace and will put up a Knox & Osborne.
WESTERN or MOUNT JACKSON, Sonoma county. Have one small Almaden furnace built by Winterburn.
WASHINGTON MINE, Napa county. Has an Almaden furnace with Colt condenser.
OAKVILLE MINES. Has three Luckhardt furnaces. (No work done during 1874.)
AMERSON, Sonoma county. Has one retort; commenced running in December.
COMSTOCK MINE, Santa Clara county. Has one retort.
ELGIN MINE, Colusa county. Has one retort.
STATTON MINES, San Benito and Merced counties. This is a group of 12 mines consolidated in one company. Have one retort running and will erect a Knox & Osborne furnace in the Spring.

The following list of quicksilver claims give promise of being mines when developed, and will have furnaces or other reduction works this year. The list is not supposed to embrace one-half of the good prospects which will be so improved:

The Los Prietos claim, Santa Barbara county; Jeff Davis, San Luis Obispo county; Todoo Santa, San Luis Obispo county; Pine Mountain, San Luis Obispo county; Quien Sabe, San Luis Obispo county; Amador, El Dorado county; Kentuck, Sonoma county; Socrates, Sonoma county, will be opened and ready for furnace. Flagstaff, Sonoma county; Mercury, Sonoma county; Wall Street, Lake county; Columbia, Lake county; London, Lake county; El Madre, Napa county; Georgia, Sonoma county; Cedar, Napa county; Montezuma, Colusa county; Empire, Colusa county; Cochran, San Luis Obispo county; Live Oak, Sonoma county; Hercules, Sonoma county; Emma, Sonoma county; Illinois, Sonoma county; Peerless, Napa county; Thompson, Sonoma county; Central, Napa county; American, Lake county; Yosemite, Napa county; Bacon mines, Sonoma county; Pilot Knob, Lake county; Alice Cross; Brandt mine, Sonoma county; Lytle, Trinity county; Boston, Trinity county; Edith, Sonoma county; Empire mine, Mendocino county; Gibson & Phillips, San Luis Obispo county.

There are many other claims being worked, which have yet assumed no prominence, and which are not mentioned above. We are unable to give any figures of the quicksilver product of the year. Most of the metal is consumed at the mines in the different mining States and Territories, the Comstock mines using the largest amount of any one section. The item of quicksilver, at its present prices, is an important one to the mining interests. How much we have consumed, it is difficult to tell. It all goes out of the State, and none of it ever returns. When our mills lose from half a pound to a pound and a-half for every ton they work it does not take long to use several tons of mercury. By the statistics of the Central Pacific Railroad Company, we see that 432,635 pounds of quicksilver were shipped from this city as through freight, (which means that it went out of the State), and 36,444 pounds were shipped from San Jose. As local freight they carried 47,007 pounds. Our exports by sea from this city from 1859 to 1874 inclusive were as follows:

Quicksilver Exports.

Year.	Flasks.	Value.
1859.....	3,367	\$ 126,202
1860.....	8,962	318,320
1861.....	35,218	1,112,654
1862.....	35,707	1,169,197
1863.....	26,060	846,748
1864.....	37,282	1,227,963
1865.....	41,266	1,373,283
1866.....	30,789	1,062,940
1867.....	28,824	920,726
1868.....	43,607	1,390,054
1869.....	28,365	947,671
1870.....	19,959	669,015
1871.....	11,244	352,125
1872.....	14,721	475,414
1873.....	6,169	202,495
1874.....	6,388	219,525
Totals.....	365,788	\$14,226,441

The following table shows the destination of the quicksilver shipped by sea:

New York.....	Flasks.	Value.
Central America.....	2,405	\$23,300
China.....	547	54,472
Japan.....	1,150	94,500
British Columbia.....	83	11,930
Australia.....	2	220
Mexico.....	50	7,500
New Zealand.....	1,146	119,654
Totals.....	5,504	\$498,330

Quicksilver mining is destined to become even more important to California than it has ever been before, for we have the only mine of the kind in the United States.

During the past year

Copper Mining
Has not been in so flourishing a condition as one would suppose. All the copper mined is shipped from here to Liverpool for reduction, none of it being worked here. The high rates of freight ruling during most of the year have deterred owners from shipping, and the mines have in consequence not been worked very

actively. The figures of export for the year, which are the figures of production, show a lower average than they have since we began to mine copper here. The exports of copper from 1861 to 1874, inclusive, were as follows:

Year.	Tons.	Value.
1861.....	1769	\$ 122,581
1862.....	3389	236,194
1863.....	6993	512,925
1864.....	14315	1,994,660
1865.....	25380	1,821,360
1866.....	19813	1,383,852
1867.....	7833	421,546
1868.....	6077	227,925
1869.....	2542	117,133
1870.....	2254	103,732
1871.....	2562	121,960
1872.....	2198	116,970
1873.....	1832	114,862
1874.....	1352	67,400
Totals.....	96,674	\$7,439,080

Lead.

In a previous portion of this article, we mentioned the product of the Cerro Gordo base bullion mine. The lead refined in the city in 1874 was 20,000 tons, and 10,000 tons were shipped. San Francisco is fast becoming one of the most important lead refining centers in the world. For a few years past the bullion from the Cerro Gordo mines with some from Nevada has been refined at Selby's works at North Beach, and last year the amount refined was 12,000 tons, of which 10,000 was exported. Every year this establishment grows, and we hope are long to say that the whole product of the Pacific is being manufactured here. Many new mines producing lead have been opened of late, and the industry is fast growing to large proportions.

A very important article to every one here as elsewhere is

Coal.

California though abounding in everything else has very little true coal. The lignites of some of the counties are now being utilized however, and several new coal mines were opened during the year. The receipts of coal in this city from all Pacific Coast sources have largely increased during the year save alone from Bellingham Bay and the Rocky Mountains. About 325,520 tons were received in this city from Pacific Coast mines, including 47,982 tons from British Columbia. The receipts of Mount Diablo coal during 1874 were 203,255 tons. The production of California, as represented by the Mount Diablo mines, has increased 33,255 tons. The deposits at Lincoln are, if the quality of coal be all that has been said of it, of the greatest importance to the future industrial development of the State. Other discoveries were made in the southern part of the State earlier in the year, but nothing has since been heard of them as is the case with several other localities.

Conclusion.

In concluding our remarks on California mines we most heartily congratulate our miners on the result of their year's work. Everything is in a prosperous condition and the late rains will make plenty of business for all hands for some time to come. As yet, however, there is not an abundance of snow supply in the mountains for this season's purpose, but it is to be hoped that before the winter closes it will be piled deep and high in the mountains and transfer itself gradually into the miners' greatest want, water. Several of the new districts opened this year have yet to prove their worth and by spring we expect to hear of many new mines being opened.

We have in this article confined ourselves entirely to California mining matters with the exception of the statistics relating to bullion productions. We are unable for want of space to enter into any details of neighboring States and Territories.

They have made on the Comstock lode, in Nevada, some of the greatest mining developments ever made in the world. We have of late given considerable space to detail these discoveries, and regret that we have no space here to speak at length concerning them. The details are, however, fresh in everybody's mind, as they are attracting the attention of the whole world.

The stock excitement in San Francisco consequent on these discoveries has been general, and many people have made large fortunes. Of this, also, we have given details from time to time. The aggregate amount of sales at the San Francisco Stock and Exchange Board during 1874 was \$260,471,915, about double that of any previous year. The sales last month alone were \$50,000,000.

C. H. Stover.....	17	375	18 75
G. R. Eckley.....	8	750	37 50

And in accordance with law, and an order of the
Board of Directors, made on the 7th day of December,
1874, so many shares of each parcel of said stock as
may be necessary will be sold at public auction at the
office of the Company, 321 Battery street, San Francisco
Cal., on Monday, the twenty-fifth day of January, 1875,
at 12 o'clock, m., to pay the delinquent assessment, together
with costs of advertising and expenses of sale.

Office, 321 Battery street, San Francisco, California,
(office of U. S. Internal Revenue Collector.)

POSTPONEMENT.—The date of payment of assessment
on the above described stock is deferred until Monday,
February 1st, 1875. **ABRAM SHEAR, Secretary.**

California Beet Sugar Company.—Loca-

tion of principal place of business, San Francisco, Cal-
ifornia. Location of works, Sonoma, Santa Cruz County,
California. Notice is hereby given, that at a meeting of the Board of
Directors, held on the 23d day of December, 1874, an as-
sessment of Five Dollars per share was levied upon the
capital stock of the corporation, payable immediately in

United States gold coin, to the Secretary, at the office
of the Company, 214 California street, San Francisco, Cal.
Any stock upon which this assessment shall remain un-
paid on the 31st day of January, 1875, will be delinquent
and advertised for sale at public auction, and unless
payment is made before, will be sold on the 21st day of
February, 1875, to pay the delinquent assessment, together
with costs of advertising and expenses of sale.

Office, No. 314 California street, San Francisco, Cal.

California Consolidated Mill and Mining

Company—Location of principal place of business, San
Francisco, California. Location of works, Nashville, El
Dorado county, California. Notice is hereby given, that at a meeting of the Directors,
held on the 14th day of January, 1875, an assessment of
(\$1) one dollar per share was levied upon the capital stock
of the corporation, payable immediately, in United States
gold coin, to the Secretary, at the office of the company,
408 California street, room 15, San Francisco, California.

Any stock upon which this assessment shall remain un-
paid on the sixteenth day of February, 1875, will be delin-
quent and advertised for sale at public auction, and un-
less payment is made before, will be sold on Friday, the
5th day of March, 1875, to pay the delinquent assessment,
together with costs of advertising and expenses of sale.

Office, room 16, 408 California street, San Francisco,
California.

Confidence Mining Company—Location

of principal place of business, San Francisco, California.
Location of works, Tuolumne County, State of Califor-
nia. Notice is hereby given, that at a meeting of the Board of
Directors, held on the sixteenth day of January, 1875, an
assessment of thirty (30) cents per share was levied upon
the capital stock of the corporation, payable immediately
in United States gold coin, to the Secretary, at the office
of the company, 210 Battery street, San Francisco, Califor-
nia.

Any stock upon which this assessment shall remain un-
paid on Tuesday, the twenty-third day of February, A. D.
1875, will be delinquent, and advertised for sale at public
auction, and unless payment is made before, will be sold
on Wednesday, the seventeenth day of March, 1875, to pay
the delinquent assessment, together with costs of adver-
tising and expenses of sale.

Office, 210 Battery street, San Francisco, Cal.

Electric Mining Company—Location of

Principal place of business, San Francisco, Cal.
Notice is hereby given that on the following
described stock, on account of assessment, levied
on the twenty-eighth day of November, 1874, the
several amounts set opposite the names of the respec-
tive shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.

And in accordance with law, and an order of the
Board of Directors, made on the 28th day of November,
1874, so many shares of each parcel of said stock as
may be necessary, will be sold at public auction at the
east room of Maurice Dore & Co., No. 326 Pine street,
San Francisco, on the 26th day of January, 1875, at the
hour of 12 o'clock, m., to pay the delinquent assess-
ment thereon, together with costs of advertising
and expenses of sale.

T. B. WINGARD, Secretary.

Office—Room 13, No. 318 California street, S. F.

Gen eva Consolidated Silver Mining Com-

pany. Principal place of business, City and County of
San Francisco, State of California. Location of works,
Crescent Mining District, White Pine County, Nev-
ada. Notice is hereby given that at a meeting of the Board of
Directors, held on the 21 day of January, 1875, an assess-
ment of twenty-five cents per share was levied upon the
capital stock of the corporation, payable immediately, in
United States gold coin, to the Secretary, at the office
of the Company, Room 14, 302 Montgomery street, San
Francisco.

Any stock upon which this assessment shall remain un-
paid on the 8th day of February, 1875, will be delinquent,
and advertised for sale at public auction, and unless pay-
ment is made before, will be sold on Monday the first day
of March, 1875, to pay the delinquent assessment, together
with costs of advertising and expenses of sale.

Office—Room 14, No. 302 Montgomery street, S. F.

Gold Mountain Mining Company—Loca-

tion of works, Lower Rancheria, Amador County, Cal.
Notice is hereby given, that at a meeting of the Board of
Directors, held on the 4th day of January, 1875, an assess-
ment of twenty-five cents per share was levied upon the
capital stock of the corporation, payable immediately, in
United States gold coin, to the Secretary, at the office
of the Company, Room 14, 302 Montgomery street, San
Francisco.

Any stock upon which this assessment shall remain un-
paid on the 8th day of February, 1875, will be delinquent,
and advertised for sale at public auction, and unless pay-
ment is made before, will be sold on Monday the first day
of March, 1875, to pay the delinquent assessment, together
with costs of advertising and expenses of sale.

Office—Room 14, No. 302 Montgomery street, S. F.

Orleans Mining Company—Location of

principal place of business, San Francisco, Cal. Loca-
tion of works, Grass Valley Township, Nevada County,
Cal. Notice is hereby given, that at a meeting of the Trust-
tees held on the 4th day of January, 1875, an assessment
(No. 2) of one dollar (\$1) per share was levied upon the
capital stock of the corporation, payable immediately, in
United States gold coin, to the Secretary, at the office
of the Company, Room 8, 315 California street, San Fran-
cisco, Cal.

Any stock upon which this assessment shall remain un-
paid on the 8th day of February, 1875, will be delinquent
and advertised for sale at public auction, and unless pay-
ment is made before, will be sold on Tuesday, the 2d
day of March, 1875, to pay the delinquent assessment, to-
gether with costs of advertising and expenses of sale.

Office—Room 8, No. 315 California street, S. F.

Germania Mining Company—The Annual

Meeting of the stockholders of the Germania Min-
ing Company, for the purpose of electing a Board of
Directors, and such other business as shall properly
come before the meeting, will be held at the office of
the company, room 16, 408 California street, San Fran-
cisco, California, on the 1st day of February, 1875, at
the hour of 1 o'clock p. m.

J. W. TRIPP, Secretary.

"Golden Rule" Silver Mining Company—

Location of principal place of business, San Fran-
cisco, Cal. Notice is hereby given, that on the following
described stock, on account of assessment levied
on the 8th day of December, 1874, the several amounts
set opposite the names of the respective shareholders,
as follows:

Mining Machinery.

TEATS' PATENT FURNACE.

TEATS' PATENT FURNACE

For Roasting, Desulphurizing, Chloridizing and Oxidizing Ores, etc. For the reduction of Gold, Silver, Lead and other ores, saving a larger percentage, at less cost, than any other invention now in use. Chloridizing Silver ore more thoroughly, in less time, with less fuel, salt and labor; also roasting Lead ore preparatory to emitting, better and cheaper than any other invention. The Furnace is so constructed that one man, of ordinary ability, tends five or more furnaces, controls them with ease adding heat or air, stopping or starting at will; charging and discharging with ease. Also, Patent "Conveying Cooler," for conveying and cooling roasted ores, heating the water for amalgamation and the boilers at the same time. Saving the large space in mill (covered with brick or iron), and the labor of two men per day, exposed to the poisonous chlorine gases. Also, Patent Air Blast "Dry Kiln," for drying ores direct from the mine or breaker, saving fuel and labor heretofore necessary in drying ores for dry pulverizing. For description refer to MINING AND SCIENTIFIC PRESS, No. 18, October 31, 1874. For particulars address

TEATS & BREED,

No. 12 West Eighth Street, Cincinnati, Ohio

Circulars, &c., will be furnished, if required.

7v26-1f

JOHN TAYLOR & CO.

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits. They are constructed so as to apply steam directly into the pulp, or with steam hot water, as desired.

This Amalgamator Operates as Follows.

The pan being filled, the motion of the miller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Sellers made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill-men are invited to examine these pans and settlers for themselves, at the office, 229 Fremont Street, San Francisco.

IMPROVED HOISTING ENGINES.

HOISTING ENGINES.

Descriptive Circular
and Prices.

COOK, RYMER & CO.'S Celebrated Hoisting Engines have been too long in use on the Pacific Coast to require any special recommendation from us. We refer with confidence to any one of the hundreds now in use. We simply state that they still maintain their old reputation, the manufacturers not having followed the now too common practice of reducing the quality of material and workmanship for the sake of competing with cheaper engines. For details of sizes send for price list. We desire to call particular attention to our new

MINING HOISTING ENGINES.

(Manufactured by the same parties.)

Which have just been introduced on this Coast. The plans and specifications are the combined efforts of our most successful MINING ENGINEERS, and the result is the most complete

DOUBLE-DRUM HOISTING ENGINE

Ever built. Their advantages will be seen at a glance by any one familiar with the necessities of a mine. One of these engines may be seen at work in the Belcher mine, and one in the Ophir, on the Comstock lode, to both of which we refer. We have all sizes of these engines constantly on hand. Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

[PATENTED MAY 26TH, 1874.]

Price Reduced to 16 CENTS Per Pound.

SAN FRANCISCO, November 10th, 1874.

To Supls. of Quartz Mills and Mining Men generally:

1v29-3m

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburg Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent. cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are: increased cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 60 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to
CAST STEEL SHOE & DIE CO., Room 1, Academy Building, S. F.

Sole Agents for WRIGHT'S
BUCKET-PUNGER STEAM PUMP.
ALWAYS RELIABLE.

THE SELDEN DIRECT-ACTING STEAM PUMP,

A. CARR, Manufacturer & Proprietor.

Patented

Aug. 2d, 1870.

Dec. 20th, 1870.

Combining simplicity and durability to a remarkable degree. Its parts are easy of access, and it is adapted to all purposes for which Steam Pumps are used.

As a Mining Pump it is Unsurpassed.

—ALSO—
STEAM, GAS & WATER PIPE, BRASS WORK STEAM & WATER GAUGES, FITTINGS, ETC.

CARR PATENT STEAM RADIATOR.

Send for Price List and Circulars. Address,

A. CARR,

10v28-ly 48 Courtland Street, New York

BLAKE'S PATENT STEAM PUMP—MORE THAN 7000 IN USE.

MINING PUMPS,
TANK PUMPS,
MARINE PUMPS,
FIRE PUMPS,
Plunger PUMPS,
SUGAR PUMPS,
OIL PUMPS,
Brewry PUMPS,
Tannery PUMPS,
Irrigating PUMPS,
FARM PUMPS,
ACID PUMPS,
Wrecking PUMPS,
FEED PUMPS.

The BLAKE PUMP may be seen in many of the principal mines of California and Nevada. More than 7,000 have been sold, and we refer to any one found in use. Send for our large and handsomely illustrated Catalogue giving prices and details of over 100 different sizes. A large stock of all sizes on hand at the Machinery Depot of

TREADWELL & CO., San Francisco.

1874. A GRAND SILVER MEDAL. 1874.

PARKE & LACY, Sole Agents,
310 California Street,
SAN FRANCISCO.

The highest and only prize of its class given to any Vertical Engine was awarded to the

HASKINS ENGINES AND BOILERS,
BY THE

MASS. CHARITABLE MECHANICS' ASSOCIATION,
at their Fair in Boston, in competition with the
Baxter, New York Safety Steam Power
and the Sharpley Engine.

Cazin's Combination Ore-Sizer and Con-
centrator—One Plunger System.
[Covered by Letters Patent of July 2d, 1872, and recent
applications.]

Containing a sizing apparatus, (revolving screen) de-
livering two or four sizes of ore to two or four rows of
sieves, each row independent of the other, and each
having 5 sieves, each row concentrating according to
specific gravity the special size automatically fed unto
it, resulting in the simultaneous continual delivery of
separated materials, working 2d and 3d-class ores into
1st-class ores of perfect cleanliness. It thoroughly sepa-
rates native gold or copper from quartz or any other
lode matter, galena, and silver sulphurets from
pyrites, barite and quartz, and pyrites from quartz.
Added to a battery of stamps these machines consti-
tute a full system of ore concentration, sufficient in
most cases for the requirements of western mines, with
a capacity of 15 or 20 tons per 24 hours.

For particulars apply to,

CENTENNIAL PACKING.

SELF-LUBRICATING.

FOR
Locomotive
Marine and
Stationary
ENGINES.

FOR
Steam Pumps
AND
Hot or Cold
Water Pumps
OF ALL KINDS.

The CENTENNIAL is composed of the finest Hemp, made in strands or sections, of different sizes, each being saturated in a composition of pure German Black Lead and Tallow and covered with a braiding of the best Italian Hemp to be found in the market. It is manufactured in a shape the most convenient to use and handle, and gives from 50 to 100 per cent. more length compared with an equal weight of other makes. It runs with less friction on the rod than any other Packing made, from the fact of its being so perfectly soft and pliable, and so well lubricated so to require a minimum pressure on the rod. It cuts off smooth and makes perfect joints, is easily adjusted to any size rod, and only requires occasionally a new ring to keep the stuffing box full. ENGINEERS, TRY IT. For sale in any quantity by TREADWELL & CO., San Francisco.

Reduction of Silver Ores.

First Lecture of the Scientific Course by Prof. Becker.

Our annual mining review crowded out last week the lecture by Dr. Becker, which was delivered at the Mechanics' Institute, last Saturday week. We give, however, below a summary of his remarks. This was the first lecture of the season of the scientific course, to be given under the auspices of the Regents of the State University and the directors of the Mechanics' Institute.

The Professor, after a few preliminary remarks on the condition of metals as they occur in nature, said that gold never occurs unaccompanied by silver, and the same is true of lead, and the deposits of these two metals generally contain silver in sufficient quantities to pay for its extraction. Copper, too, is very often accompanied by silver, and minerals containing silver as an essential element are sometimes found in large quantities. Native metallic silver accompanies native gold, and is also, though much more rarely found alone. The most important ore of silver is galena, or, properly speaking, a lead ore—the sulphide of lead. All the silver obtained in Great Britain, most of that derived from continental ores, and an immense proportion of the bullion obtained in America is reduced from galena, although, when the value of silver in this ore is great, it is generally called a silver ore, instead of an argentiferous lead ore, just as the product of its reduction is called on this coast, but nowhere else, base bullion, instead of argentiferous lead. There is a whole series of antimony compounds of silver, which are generally very rich, but always very troublesome. It is antimony which renders such ores refractory.

Treating Pure Ores.

The more common ores are generally treated for extraction by melting down in such a way that a fluid metal and fluid slag are formed, which separate in virtue of their different specific gravities, and may be tapped from the furnace at different levels, the metal being cast into marketable bars and the slag thrown away. A lead ore containing but fifty per cent. of metal would be but a second-class material. A silver ore containing the same percentage would be worth over \$18,000 per ton, but such valuable ores are not found by the ton. Silver ore of such richness that the metal bears a sufficient proportion to the whole weight to allow of a proper separation by the ordinary methods never occurs. We are therefore compelled to make up the necessary weight and volume by alloy. Three metals perform this office under different circumstances; these are lead, quicksilver and copper. Lead is the most widely used and copper is the most rarely employed.

Lead Ore.

Lead ores are treated either in a cupola furnace or in a reverberating furnace. In melting lead ores the fire is kept low and much air is admitted until a portion of the galena is roasted. The sulphur of the galena combines with the oxygen and forms sulphurous acid gas, which passes up the chimney. The oxygen attacks the lead and it becomes oxide of lead, a compound which, when tolerably pure, is known as massicot, much used in glass-making, etc. The fire is then made up and the air excluded as much as possible. The sulphur in the sulphide of lead attacks the oxygen in the oxide of lead formed by roasting, and they form more sulphurous acid, which also goes up the flue, leaving the metallic lead. This can then be tapped from the furnace and cast into bars. When the ore is argentiferous, the silver sulphide is decomposed in the same way and at the same time, and the silver is found in the lead bars.

Impure and Poor Ores

Are treated in the cupola furnace. The ore is generally roasted before melting. The gases formed by combustion are forced out of the top furnace by air driven by machinery near the bottom of the furnace and the metal accumulates below this air-nozzle. Meantime, of

course, the column of material constantly sinks, and fresh ore, flux and fuel are from time to time charged to keep the furnace full. The silver again follows the lead.

The Treatment of "Base Bullion"

Varies with circumstances. If it is rich, means are taken to extract the silver immediately. If it is poor, it is better to submit it to the processes which will effect a concentration of the silver in a comparatively small mass of lead, and thus extract the silver from this concentrated material.

The processes of concentration in use are the crystallization and the zinc processes. Pattison's crystallization process depends on the remarkable properties of alloys of lead and silver in regard to fusibility. Alloys frequently melt at a lower temperature than either of the metals of which they are composed. This is the case with some of the alloys of lead and silver. The process of desilverization by zinc depends on the tendency of zinc to form alloys

Road and Farm Locomotives.

One of our Eastern correspondents, W. C. Quimby, sends us some notes from the Eclipse Machine Works, located at Hamilton, Ohio, and conducted by the Owens, Lake & Dyer machine company. The works are among the largest of the kind in the country, and some of their productions are specially adapted to the Pacific Coast. Prominent among the articles made there are their traction engines, or road and field locomotives, an engraving of one of which appears on this page. They are claimed by the manufacturers to be superior to any of the English engines of this class, it being especially adapted to the wants of Americans; such as hauling heavy loads over uneven ground, running threshing machines, saw-mills, and other machinery. It has not been tested in plowing, reaping, etc., but if such a thing can be successfully accomplished by any

TRACTION ENGINE, OR ROAD AND FIELD LOCOMOTIVE.

with silver and its lack of tendency to form them with lead.

Cupellation.

The silver is obtained from the rich lead by cupellation, a process based upon the greater tendency of lead than silver to oxidize. The product of cupellation is refined bullion, consisting of silver and whatever gold there may have been in the ores treated.

Chemical Method.

Besides the methods of extraction referred to, there is a considerable number of processes for the extraction of silver from its ore by fluid solvents, the silver being subsequently precipitated from solution by chemical methods. These processes have many advantages over smelting, requiring little fuel in comparison, enabling the treatment of very poor ores and making quick returns. Their use is yet quite limited, because they require, as thus far developed, material nearly free from several very common impurities.

The average daily shipment of ore during the last week from the Crown Point mine has been 500 tons; Ophir, 260 tons; Hale & Norcross, 100 tons; making a total daily yield of 1,725 tons of first-class ore, from five leading Comstock mines. The Sierra Nevada, Chollar-Potosi, Woodville and several other mines are also taking out considerable quantities of ore.

The ditch belonging to the Mokelumne bill canal and mining company broke Monday last, somewhere between Mosquito gulch and the point where the water is taken out of the river. It had not been repaired at last accounts.

The Alameda mine, Tuolumne county, lately passed into the hands of a San Francisco company, who are now developing it.

traction engine, our correspondent thinks this one will do it. He says he saw one of these engines that had been doing duty for over a year, hauling from 4,000 to 5,000 feet of green oak lumber from the interior of the country to the works of the company. Ten tons of pig iron is the usual load from the depot to the foundry. Those interested can get details of work, price, etc., by corresponding with the company above referred to.

READERS, who are able, should write more for the MINING AND SCIENTIFIC PRESS. Among the miners, engineers and millmen who read this paper, there are a host who have both the education and practice to fit them for furnishing articles that, through our paper, would materially benefit present workers and future generations of toilers yet to be. Noble and intelligent men are not more frequently met with in other callings, and yet how few are they who improve their talents by way of writing for the PRESS. We do not believe it is for the want of a generous disposition toward others, but rather a lack of self-esteem and energy. Now, we will say write for our columns. You will perform a noble duty to inform others that they may work uprightly in places that you, as pioneers, have had to feel your way through. It will improve yourselves to write. We ask all to send us correct information, and we will put it in shape if it needs dressing up.

MONTANA MINING DECISION.—The Secretary of the Interior has affirmed the decision of the Land Office in the case of the application of the patent for the General Lode, situated in Montana. The decision says that all lode claims must be governed by the laws in force on the date of the location, and cannot exceed 100 feet of surface width, unless the local laws at that time will permit.

Mining Matters in Congress.

Congress has as yet done nothing of importance with reference to the bills which are of general interest to the mining community. Several bills are, however, pending, which are important. The "Negley amendment," which was laid over from last session has not yet been considered. This amendment to the Act of May 10th, 1872, provides that all companies or persons owning claims on the Comstock lode shall make applications for patents within six months from the date of the passage of the amendment, and will receipt for the patent six months after application. It also compels owners of those mines to which patents have already been issued to receive such patents. In some cases the patents to mines on the Comstock, though made out, have never been taken from the Receiver's office, because the patent specified that a certain royalty must be paid to the Sutro Tunnel Company, when the tunnel is completed. The mining companies will fight this matter, and do not want the patents with this provision therein. Consequently they have never taken them from the Receiver's office.

Pratt's Bill, which provides that all quartz lodes which have produced \$5,000 or upward, shall file applications for patents within one year, was also laid over for last session. Eastern dispatches state that this bill will shortly come before the Public Land Committee for action.

The Ward Bill, which provides that all miners must patent their claims, upon which \$500 has been expended, will also come before the Committee shortly.

Senator Sargent has introduced a bill which is of great interest to foreign corporations and owners of mines, as follows:

That in cases where foreigners or foreign corporations have purchased mining claims for a valuable consideration, of citizens of the United States who had complied in the location and possession thereof, prior to same, with the laws of the United States governing the same, and such purchase was made prior to the date of the approval of the Act "to promote the development of the mining resources of the United States," approved May 10, 1872; and when such purchasers shall have complied with the said law in the working of the same, and shall apply for patents thereof, as in other cases, and pay to the United States the price thereof as provided by law, patents shall issue to such parties in the same manner and to the same effect as in other cases.

Sec. 2. That in cases where application shall be made for patent to mining claims by citizens of the United States, being bona fide owners thereof and in possession of the same, patent shall not be refused therefor on the ground that one or more of the locators thereof may have been foreigners at the date of location; provided, that said location shall have been made prior to the 10th day of May, 1872.

This bill has been reported on favorably by the Committee on Mines and Mining, with a few unimportant amendments.

The famous McGarraban has turned up again in Congress on the New Idria quicksilver mine business, and for once he has made a point. The House Judiciary Committee has agreed to report and recommend the House to pass a resolution directing the Commissioner of the General Land Office to institute legal proceedings in the name of the Government of the United States against the New Idria mining company, for the recovery of the quicksilver mine now held by it, and of some \$7,000,000 alleged to have been illegally taken from said mines; also allowing all persons to appear in these proceedings and have an opportunity to establish title. This is intended for McGarraban's benefit. The resolution also provides for proceedings for the appointment of a receiver, and directs the Interior Department to withhold the issuance of patents to the New Idria company, and stop proceeding in the Cerro Bonito, Johnson, Fourth of July and Boston quicksilver mining claims until the suit to be instituted by the Commissioner of the General Land Office shall have been finally determined.

CORRESPONDENCE.

Cherry Creek Mines.

EDITORS PRESS:—I have been wondering of late why it is, that so little mention is made of the mines in this section, but I suppose it is all owing to the deep interest taken in the wonderful developments, made, and being made in the all-absorbing Comstock.

The mines of this, the Cherry Creek District were discovered two years ago last June, and are just beginning to show their colors, and presaging it may not come amiss to your numerous readers, I will give you a few notes in regard to their progress in the way of development and increase in the yield of bullion. While the unbouded wealth of the famous Comstock lode is attracting the attention and exciting the envy of the whole mining world, not only in America, but throughout all Europe, we, of Eastern Nevada, should not be entirely ignored, although we cannot as yet, boast of any "big bonanza;" but as our mines are situated only about 400 miles east of Virginia City, and pitching to the west we hope soon to strike it; and, in fact, are liable to open into it at any minute.

The work of prospecting and developing the mines of this district, has progressed slowly, but very persistently, for the past two years, with varied results. At times the prospects were very bright, at other times the outlook for the future wore a very gloomy one, but the great strength of the ledges, together with the favorable indications to be seen at nearly all points along the surface encouraged the owners of some of the principal mines to push their explorations further and deeper, which they have done with very gratifying results.

The great mineral belt of Cherry Creek traverses the mountain range diagonally, from S.W. to N.E. for a distance of from six to eight miles.

There are two large and heavy ledges, one on the west, and one on the east side of this mineral belt, and which are traceable nearly the whole distance, and in which lay most of the principal mines of the district, and are known as the upper and lower mineral belts. These ledges are cut in places by deep cañons and gulches, but are traced by their croppings as they appear on the high ridges that make down from the main mountains to the east, showing the main mineral belt to be very regular, as indicated by the formation and stratification of the country rocks which are quartzite, porphyry and slate. The country rock on the west of the mineral belt is mostly lime, that on the east, quartzite and porphyry. The course of these main ledges is north 15 degs. to 20 degs. east, but there are some exceptions to this rule, however, as there are a number of ledges running nearly north 70 deg. west, and it is yet a question which will prove the most lucrative the east and west, or the northerly and southerly ledges. Each have their advocates and both have strong arguments in their favor. Time will tell.

The principal companies now operating here are Geneva Cons. M. Co., owning the Teacup and Geneva ledges, the former on the upper, and the latter on the lower belt; the Cherry Creek M. & M. Co., owning the Eschequer ledge on the lower belt; the Star M. Co., owning the Star and Grey Eagle mines, which are easterly and westerly ledges, but are claimed to be on the lower belt. The Geneva Co. have a shaft on the Teacup ledge 250 feet deep, showing a very strong vein, carrying a large amount of very high grade ore, and having every promise of a large and rich mine. The company have as yet worked only their first-class ore from this mine, which has pulped from \$150 to \$1200 per ton. The ore has mostly been worked in Thompson's two-stamp mill, with a large size Hepburn pan (capable of working from 3½ to 4 tons per day) with very satisfactory results.

On the Geneva mine they have a shaft down about 60 feet and are sinking as rapidly as possible. This ledge, showed on the surface ore of the largest and finest bodies of ore ever found in the district, and is sure to develop into a large and rich mine. The Teacup carrying more high grade ore than the Geneva, is why they have worked it more extensively. That this company have a very valuable property is now beyond question, their mines have thus far paid all the expenses of development, something quite unknown in the history of silver mining in this State.

The only other mine on the upper belt which has been explored to any extent is the Chance, belonging to Geo. Treat, and others of San Francisco. On this ledge they have a large shaft down 100 feet, from which a large amount of high grade ore had been taken; they have a fine prospect and if all indications do not fail they will have a good mine. There are several other claims on the upper belt which promise well, and will probably prove as good, if not better than either of the above, among which are the Pine Nut, Union, Baltic, and several others.

The Eschequer, on the lower belt, is now one of the most promising mines in the district. On the surface they have a body of rich ore, but from some cause or other it depreciated in quality and quantity after sinking from 25 to 30 feet, and for a while work was suspended entirely. Recently they have cut their ledge by a tunnel, driven in from the base of the hill, at a depth of 168 feet below the old workings, and have opened into a large and rich body of ore, which appears to be quite extensive. It is known to be 12 feet wide and 60 feet in length, with no apparent depreciation in quality or quantity in either direction. The company can very readily take out enough ore to repay them for all their outlay, and have a magnificent property left. The walls of the Eschequer are a gray porphyry, and wherever the walls have been found on this, the Veal Madre of the district, from the Geneva on the south to the Victoria on the north, it shows the same general characteristics.

The Star ledge, situated on the same ridge as the latter, and perhaps one-fourth of a mile distant, is now looked upon as the Star mine of the district, and as far as the shipment of bullion goes, it is certainly entitled to that name, it having shipped more than any other mine in the district, the shipments from this mine alone for the month of December amounting to about \$60,000. They are now taking out from 10 to 15 tons of ore per day, that pulps from \$100 to \$200 per ton. They have a shaft down about 150 feet, with drifts running each way from the shaft following the vein, which ranges from four to six feet in width.

Adjoining them on the west is the Gray Eagle, with a shaft 100 feet deep, showing a beautiful vein from three to five feet thick, and having all the characteristics of the Star. I believe it is the intention of the Star company to erect a large mill at an early day, for the reduction of their own ores. They have one of the finest properties in Eastern Nevada, and one that will make itself known in stock circles at no distant day.

At Egan Canon.

Four miles south of Cherry creek, the San Jose company are working their mine, the Gilligan, with a full force of men, and with very cheering results. They keep their 20 stamp mill constantly running on their own ores, which are yielding well. This mine was discovered and worked quite extensively as early as 1864; and has been prospected to a greater depth, and more extensively along the ledge than any other mine in this part of the State, and shows throughout a very strong and persistent vein of good ore, and will under the able management of General Rosecrans richly repay the owners, who have with so much confidence invested their money in it. There are a number of other mines in the district which are being prospected in a small way, all of which are very encouraging, while some of the best prospects are laying idle. One of the best features of the mines of this district is that they are large and traceable for a long distance, and evidently from the explorations already made, carry some heavy chimneys of high grade ore. The ores throughout the district are very free, and readily yield their precious metals by the application of the ordinary milling process. I don't know of any ore in the State that can be milled to as high a percentage of the assay value as these can. The ores of the two belts differ materially. Those of the lower invariably carry from \$6 to \$15 per ton in gold, while the upper belt has none; they also contain less copper and more iron. All the mills in this vicinity are now running, and have been for a number of months—27 stamps in all—and the bullion shipments amount to from \$2,000 to \$8,000 every stage. Everyone anticipates a brilliant future for Cherry creek, and judging from the present outlook I think they will not be disappointed.

Cherry Creek, January 16, 1874.

FAST RIDING TO SECURE A RE-LOCATION.—Now and then, says the Sonoma Democrat, we hear of some one re-locating a quartz vein that became vacant the first of the month, for want of complying with the U. S. Mining Law. On Monday an old miner had a lawyer draw up notices for the re-location of a well known mine, and went to the vein to post them, when he had tacked up one notice he saw an acquaintance coming on horseback, who, upon reaching the spot, said "you're too late, I've got up the first notice," to which the other replied, "I don't know about that, I'll have the second up first," while the new comer run his horse for the tunnel at the same time, hauling out a paper which was supposed to be a notice. The first man ticked his second notice, and was just fifteen minutes by his watch coming five miles to have his claim placed on record. That was mighty fast time, but he was determined to be ahead somewhere in locating the claim, as he thought he was first in the idea, and that the other had accidentally got information of what he intended. Now it remains to see which will hold the claim.

PURCHASE.—Col. D. Buel has purchased the McOrackin mine, Cerbat, Arizona, from Mr. McOrackin, Chloride Jack and others, for the sum of \$240,000, and it is considered a very cheap bargain. Those who have examined this claim consider it a second Comstock. I saw some of the rock which assayed \$2,700 per ton. Men are at work taking down the mill on Colorado river, for the purpose of removing to this mine, and when once in operation, under the management of R. Stein, will, undoubtedly, give magnificent returns in gold, as the vein is enormous in size and very rich.

Sonoma County Mines.

The Sonoma Democrat gives the following concerning the mining interests of that county:

As early as 1852 there were reported discoveries of gold on Russian river, in this county. About that time one of the Kelseys, pioneers in this section, led a party to the head of the stream, in the Bel river mountains. They met with no great success and returned. The reports of gold discoveries were again revived in 1854, but soon died out.

After the discovery and occupation of the Geyser Springs, the abundant indications of cinnabar in the vicinity attracted attention. The price of quicksilver at that time was low—50 cents per pound; the cost of reduction was great, and the Almaden mine was producing a supply adequate to the demand. For these reasons no especial attention was paid to the indications of mercury everywhere visible on the surface near the Geysers.

In 1859, Col. A. C. Godwin, then the owner of the Springs, organized a mining district, located a number of claims himself, and a number of others were also taken up. These claims were afterwards consolidated into one or two companies, and some work was done upon them. The low price of quicksilver, the scarcity of labor and the lack of skill in manipulating the ore, led to loss, and finally put a stop to all work on the mines. In 1861, Col. Godwin, who had given the enterprise most of his life, sold his interests in the Springs and mines, returned to the East and was killed in the war between the States. The stock of the consolidated companies went to zero, and the mines were sold at Sheriff's sale to satisfy the demands of the creditors. Prof. Whitney, with a corps of scientists, came along soon afterwards, and with his "no view theory" in the Coast Range, extinguished the last spark of life in mining enterprises in Sonoma for the time.

Meanwhile the developments in the silver regions of Nevada, in the quartz and gravel mines of California, caused an increased demand for quicksilver. The diminished supply afforded by the Almaden company, which had passed its maximum production, gave a further stimulus to the price, and attention was again called to the indications in this section, which had not been worked successfully at the old prices.

The mountain range in which most of the mines of Sonoma Co. are located is known as the Mount Diablo range. Just west of the peak from which the range takes its name, lie the straits of Carquinez, through which the waters of the Sacramento and San Joaquin force their way and enter the Bay of San Pablo. West of the straits the mountains trend to the northwest, gradually increasing in altitude. They form the water-shed between the Sacramento and the valleys west of it to the Pacific ocean. Napa valley lies between the main range and a spur from it terminating on San Pablo bay. The great valleys of Sonoma county are formed by another spur from the same range, terminating on San Pablo bay at a point further west. This last spur forks and forms two valleys, Sonoma and Petaluma, both with a delta and frontage on the bay of San Pablo. All these spurs unite with the main range, which then passes through the northeastern corner of this county. At or near this point of intersection a rich body of quicksilver is now being developed, a deposit which bids fair to equal if not surpass the greatest in either the old or new world.

A number of mines had been opened and successfully worked in the main range, southeast of where it enters Sonoma county. Prospectors traced the croppings of the ledges along the range into this county. Granville and Green Thompson located a claim in 1872. They discovered large deposits of float ore, and took up a claim called the Sonoma. This claim was sold to a San Francisco firm who immediately built a furnace, and, by November of the same year, were reducing metal. The mine has been worked steadily, yielding a regular monthly supply of quicksilver. An excitement followed; a great number of claims were located, and rich discoveries were made. A mining town sprang up, and Sonoma county, which had long ranked as one of the finest agricultural counties in the State, was discovered to have a mining interest second only to her great wealth in wine, wool, fruit, dairy products and wheat.

This mineral district is located in the northeastern corner of the county, in the hills forming the eastern boundary of upper Russian river valley. They are about fifteen miles from Healdsburg and twenty-seven from Santa Rosa. The mountain district in which they are located is about twenty miles long by an average width of about ten miles, including the main range and the spurs from it. Two hold streams rise in the main range. They flow in a north-west direction, with the trend of the mountains, on either side of an immense spur from the main range, unite and empty into Russian river, near the northern boundary line of the county. The highest point in this spur is Geyser mountain, a rounded and beautiful peak, visible from all parts of the great valleys of Sonoma. It takes its name from the famous Geyser springs, which send up their wonderful columns of steam from a deep gorge, of which this spur is the western wall.

In this range are located some very valuable mines. Among the most prominent are the Socrates, the Flagstaff, the Sonoma, the Anna Belcher, the Rattle snake, the Missouri, the Oakland, and the Geyser. We mention these

as they are productive—all having furnaces now running, or about to commence—and with no desire to draw invidious comparisons or to disparage other claims. There is one peculiarity worthy of mention: those mines nearest the Geyser steam springs produce free mercury, the Socrates, the Flagstaff, and the Rattle snake, while those further distant produce cinnabar, which is a combination of mercury and sulphur. It is not improbable that the mines will yield during the coming summer from 1,000 to 1,500 flasks of metal a month, worth \$100 a flask. To W. A. Stuart, an enterprising merchant of San Francisco, the development of the mines in this section of the county is mainly due. He has sound judgment, untiring energy, and, above all, had confidence in the wealth of the district, risking time, money and labor when others were skeptical. It is estimated that there are a thousand people in the district. A network of good roads run throughout, and the busy din of industry and life is heard where two years ago the only trail was that of the grizzly, and the only sound the report of the woodman's rifle.

Further north there are other mines; one, the Cloverdale, is erecting a furnace, with a hillside for a mine, through which mercury seems to be evenly and thoroughly diffused. The hill has the appearance of an extinct geyser. A few miles lower, on Big Sulphur creek, the Livermore mine is erecting a furnace.

The Guerneville Mining District.

We have mentioned that Russian river broke the immediate coast range, emptying into the sea. In this section there are a number of valuable mines. The Mont Jackson and the Great Eastern are both building furnaces. The indications of a large and lasting deposit are very favorable. Many believe that they will equal if not surpass the mines in the Pine Flat district. They were only discovered during the past spring. As far as work has been done the indications are favorable, both mines having rich ore on the dump waiting for the completion of reduction works. In the same section a rich copper mine, the Olive, is now being worked.

In the vicinity of Cloverdale a chrome iron mine is worked, and regular shipments of ore are made. Of this valuable metal there is an inexhaustible supply in Sonoma county. Quicksilver mines are also being worked in the same vicinity. Our mineral wealth is in the infancy of its development. The day may not be distant when Sonoma will rank as a mining county as high as she now does for her varied agricultural resources.

THE MCGLEW FURNACE.—The Nevada State Journal says: We paid Peavine district a visit on Tuesday, and the result of our observations was most satisfactory, though it will not be known for a few days yet whether or no we are to have a prosperous mining camp in Washoe county. For the time being all depends on the successful working of the rebellions ore of the district by the McGlew furnace, just erected at a cost of something like \$6,000. If by this process the precious metals can be extracted with profit, then is the future permanency of the district assured. The result will be known within the next few days, and we hope for the best; though Mr. McGlew is quite confident there will be no trouble. By the McGlew process the ore is crushed dry and placed in a feeder at the top of the furnace. There are three flues, three feet long and twelve inches deep. As the pulp passes down the incline or main due to No. 1 it becomes heated and separated by the blast is using from the flue; thence to flue No. 2, where it is treated in the same manner; thence to flue No. 3, treated in same manner and heated to any degree of heat required; thence into the receiver, and there remains with the fires of the three flues passing over it, and giving an opportunity for the chlorine fumes to pass off with the smoke. The heat can easily be increased or diminished as required to suit the different qualities of ores. The ore after leaving the feeder instantly becomes heated by the flames issuing from the flues and a continuous heat kept up until drawn for cooling. It is then carried to the pans and amalgamated in the same manner as other ores. As we have previously stated, everything depends just now on this furnace, the life of Peavine hanging as it were by a thread, for the mines in the district are looking splendid, and yielding their usual quantity of fine ore.

The supervisors of San Diego county have appointed three road viewers to go over the road from Banner to Los Palamos and report the probable cost of opening the road to intersect the San Bernardino road to Ehrenberg. This route, it is claimed, will be twenty-five miles nearer from the Colorado river to San Diego than the present traveled road by way of San Bernardino.

THE 1000 foot level in the Gwin mine, Calaveras county, is started. It is thought rock will be struck within thirty or forty feet of the shaft, and there are good reasons for the belief that the new level will yield a larger amount than any above it. The mills are kept constantly running on a fair grade of ore taken from the 900-foot level.

THE City of Mexico Two Republics says: Several Californians, representing immense mining interests in that State, have arrived in the mining district of Bravos, Guerrero, wherewith they devote their time and capital to developing the mining interests of that district.

SCIENTIFIC PROGRESS.

The Unity of the Universe.

The Stoics delighted to dwell on the unity of the universe, and pointed out its perfect harmony. They had an anticipative view of the doctrine that heat will at last absorb all things into itself, out of which a new world will issue. The atomic theory was adopted from Democritus by the Epicureans, and was wrought into a gorgeous form by the Latin poet Lucretius. Neither Democritus nor Epicurus was a professed atheist; on the contrary, both held that the gods made themselves known to man by images or effluvia from heaven. But Lucretius pronounced his theory to deliver men from all belief in the gods and superstitious fears, and represented death as the cessation of existence. It is instructive to observe what a run there is in the present day after Lucretius, both by classicists and physicists. He is declared to be the greatest of the Latin poets, and placed above Virgil and Horace. His arguments and his rich descriptions are quoted, and students have to wade through the mantled pool of his erotics to pluck his flowers. It is curious to notice how a philosophy seeks for and creates a poetry suited to it. The philosophy of Epicurus, so prevalent among the Romans, unmentioned in "De Rerum Natura," it has to be added, in the licentious pictures on the walls of Pompeii and Herculaneum. The philosophy of Locke and Bolingbroke found appropriate verses in Pope. The subjective philosophy of Kant came forth in the grand German poetry of the beginning of this century. The physical philosophy of our day has already got a sensuous poetry in works which will doubtless be followed by others. It is because philosophy calls forth such influences, that it comes to have a sway over national character. We can believe with Montesquieu that the Epicurean philosophy exercised an influence in deteriorating the character of the Romans, in hastening their ripeness into rottenness, and determining their fall—we can understand this when we look into these fragments of obscene Epicurean verses, which have come out of the ruins of Pompeii to testify against the inhabitants. We confess that we have fears of the results when the new physics come to crystallize into the creed of the rising generation, and to lead the literature and inspire the prevailing sentiment of the age.

Dr. Tyndall has no appreciation of the benefit conferred on science by Christianity in introducing new and lofty ideas: in showing that there is only one God, and thus preparing the way for the doctrine that there is a unity in nature; in leading men to expect that there are order and wisdom through all God's works; in making the study of nature a duty we owe to God; and in giving us exalted views of the soul as fashioned after the image of God. He speaks in disparaging language of the scholastic ages, whose function it was to preserve all through the cold winter, whose seeds which had been deposited by ancient thought, and which were ready to sprout at the return of spring—he might have spoken with more respect of the medieval ages, had he reflected that in them more new metals were discovered than in all the Greek and Roman times.—*International Review*.

DISINTEGRATION OF GLASS.—A correspondent of the *Boston Journal of Chemistry* recently awarded to that journal some small flakes of glass, which were taken from an empty fruit can. The can was filled in the summer of 1873 with red Antwerp raspberries, in the usual way of canning fruit. The fruit was used out of winter, and the can cleaned and set away for future use. During the following summer when wanted for use again a "table-spoonful" of small thin flakes of glass were found in it. The can was emptied and again set away to see the result, and soon afterward flakes were again found in the can, while the glass of the can still continued to look clear and transparent. The editor of the *Journal of Chemistry* has satisfied himself that the flakes are genuine glass, and considers the spontaneous disintegration of the glass is certainly singular, but not altogether without precedent. The same result has been observed in ammonia bottles left open, and in some other instances. The change is not liable often to occur, but it may be well to examine glass fruit cans carefully, before using them.

ANOTHER EXPLOSIVE—OZOGENINE.—Foreign investigations of the actions of ozone upon certain hydrocarbons, have lately led to the discovery of an interesting substance to which the name of ozobenzene has been given. Pure ozonole, yields, under the action of ozone, acid radicals, including formic and acetic acids, and at the same time a gelatinous body separates, which constitutes the ozobenzene. When dried in vacuo, this ozobenzene is an amorphous solid, explosive to such a degree that an explosion ensues whenever it is struck or heated. The explosion of only a few decigrams of the substance will shatter the windows of a room. It is as dangerous that not more than three to five milligrams should be used for the experiment. Ozobenzene is readily and apparently spontaneously decomposed in the air, in vacuo, or in an atmosphere of carbonic acid. Water dissolves and decomposes it.

TWO GREAT SCIENTIFIC TRUTHS have been established in this century. One is the doctrine of the conservation of energy, which implies that all the physical forces are correlated, and that the sum of force, potential and actual, in the universe is always one and the same. The men who did most to prepare the way for this doctrine, such as Newton, Davy, Oersted, Herschel, and Faraday, all delighted to see God in his works, and the living philosopher who was the main agent in discovering it, Dr. Mayer, has a mind filled with the presence of God, and looks on force as the expression of the Divine power. The other great doctrine is that of development, acknowledged as having an extent which was not dreamed of till the researches of Darwin were published. How far evolution is to be carried is a disputed point among naturalists. Darwin seems to have a great antipathy to final cause; but he has somehow or other convinced himself that there is a God, and is obliged to call in three or four germs, or at least one germ, created by God. It could easily be shown that the doctrine of development properly understood, and kept within inductive limits, is not inconsistent with final cause; for we may discern a plan and a purpose, means and end, in the way in which plants and animals are evolved, and in the forms they take, which are evidently not by chance, or by blind atoms, but according to a progression foreseen from the first, and proceeding in a determined order.—*International Review*.

RESPIRATION AND NUTRITION IN PLANTS.—M. Corenwinder, says *Nature*, has contributed to a recent meeting of the Scientific Society of Lille, an account of a series of observations on the processes of respiration and nutrition in plants, wherein he holds that the process of the absorption and decomposition of carbonic acid and exhalation of the oxygen, is really a process of digestion; that the absorption and exhalation in the process is a true process of respiration, similar, in all respects, to that of animals.

By a very careful series of analysis on several varieties of plants, he has determined that the proportion of nitrogenous matter in the leaves gradually diminishes from the time that they emerge from the bud till they fall from the tree; the proportion of carbonaceous matter increases very rapidly during April and May, and there remains until nearly stationary until October, while that of the incombustible substances increases during the whole period of vegetation.

NEW APPLICATION FOR THE SPECTROSCOPE.—If the spectroscope is valuable and efficient in matters celestial it is not less so in matters terrestrial. For tests and analysis as a laboratory instrument, it becomes every day more serviceable. One of its applications is well worth notice, in testing the quality of water. In some places the water is found to be injurious to health. It is perhaps contaminated by infiltration from a sewer or cesspool. How is this infiltration to be discovered? A quantity of salt of lithium is thrown into the sewer or cesspool. After a time the drinking water is examined by the spectroscope. If the lithium line appears in the spectrum, it is a proof that a portion of the lithium salt thrown into the sewer or cesspool has found its way into the drinking water, and that the water is consequently poisoned by foul drainage. From this we see that the spectroscope may be made to do good service in protecting the public health.

PROTECTION AGAINST HAIL AS WELL AS LIGHTNING.—Observations in regard to the circumstances under which hail storms are formed, have conclusively proved that they can only originate by co-operation of clouds highly charged with electricity; therefore it was many years ago suggested that a great number of lightning rods or conductors erected on poles might protect a region from hail storms, and experience has verified this theory. We read now that it has been tried on a large scale around Tarbes, in France, where, according to a French agricultural journal, eighteen communes have been provided with such conductors, one of them being erected for every 700 acres, and that they have given full protection against both hail and lightning. This fact is important in many districts where peculiar topography renders them peculiarly liable to severe hail storms, which prove very destructive to vegetation, etc.

EFFECT OF FLAME ON AN ELECTRIC SPARK.—Mr. S. J. Mixer notices a curious effect of a gas flame on the current of a Holtz machine. The jet consists of a glass tube drawn out to a point, and the flame has a length of about an inch and a diameter of only an eighth of an inch. Inserting this between the two terminals of the machine, the length of spark obtainable was at once increased from less than ten inches to over twelve, the full distance to which the balls could be separated. The same increase was not obtained by simply inserting a conductor between the two terminals, a ball an inch in diameter only lengthening the spark about an inch.

IS HYDROGEN A METAL?—Dr. S. Worth, of Baltimore, infers from the fact that as hydrogen, occluded by palladium, is easily recovered by moderately heating the palladium, hydrogen cannot be a metal; or at least that its "occlusion" furnishes no evidence that such is a fact. The further fact that other solid bodies absorb large quantities of gases without alteration of the former he also considers further evidence that the metal hydrogen is a myth.

TECHNICAL SCHOOLS.—Where our future skilled workmen are to come from is a question which is crowding for a solution. The doctrine, or rather the total abrogation of the apprentice system has deprived the youth of the opportunity of learning trades. The result is that there are few who are learning, so that skilled labor is getting scarcer in every department of industry. It is therefore a matter of urgent importance that some method should be devised to remedy this difficulty. Of all the plans discussed there seems to be but one which promises success; that is, the establishment of technical schools. The large degree of success which has followed the introduction of these schools in some departments of our activities is strong proof of their utility in all branches. We might refer to our various schools of design and art, to our medical schools, and schools of mining and engineering.

ASTRONOMICAL SCIENCE.—So stupendous are the facts, and so bewildering are the teachings of astronomical science that it is probable but few of its statements and deductions would be believed by the masses of the community, were it not for the ocular evidence that transits and eclipses take place precisely, to the very minute, as they are calculated and predicted. These facts afford such positive demonstrations of the accuracy of astronomical measurements and researches, that all cavil and doubts have to be set aside, and the uneducated world is now compelled to acknowledge as the simple operation of the immutable laws of nature, what for countless ages had been regarded as indications of an offended deity.

MECHANICAL PROGRESS.

Economic Method of Drying Foundry Molds.

In most foundries the drying of the molds is effected by means of sheets of iron, on which a fierce coke fire is maintained. Here, evidently, is a great loss of calorific, for the drying is only effected by radiation, and in a space where the air has generally free access. In the case of large castings, such as cylinders, fly-wheels, framing etc., this plan has also the disagreeable effect of producing great heat all around, and the molds engaged in the same building suffer seriously at times. In addition to this, it is mostly necessary to employ a crane to sustain the frame, or to employ heavy materials which have to be brought to the spot and afterward carried away again, disarranging the material of the foundry and giving rise to unnecessary work.

No improved method had been attempted that we are aware of until a few months since, when M. Dehamme invented and patented a plan which was introduced four months ago into the foundry of MM. Quillaecq & Co., at Anzin, of which M. Dehamme is foreman.

The arrangement is very simple. Near the most convenient end of the mold a hole is dug in the ground, and in this is placed a coke stove, which communicates with the mold by means of a short horizontal pipe, through which all the gases of the coke pass. On the other end of the mold is mounted a chimney-pipe, the upper end of which is carried out through the roof or side of the foundry. In the chimney is a damper to regulate the draught. The stove being partially or entirely sunk in the ground, there is little or no radiation from that, and little loss of heat, and consequently of fuel, as the whole of the gases enter and pass through the mold, and are at once carried away by the pipe into the open air.

The economy is great. In certain cases in which, according to the old method, it would have required a ton of coke to dry the mold, it is effected by the new mode with one-fifth of that quantity; the saving is, however, not generally so great as this, but is said to amount on the average to 50 per cent. During the four months that M. Dehamme's system has been at work at Anzin, it has realized an economy of 600 to 700 fr. per week in the saving of coke alone, and the lighting, which, in the old time, consumed seven steres of wood per month, is now easily effected by means of a few shavings or pieces of waste wood.—*Iron*.

METALLIC FLOORS.—A method has been devised for rendering floors to a certain degree fire-proof, by employing long flat bars of thin sheet metal, with a perpendicular flange turned on each edge. Other long thin bars, which are curved or arched, and riveted at or near their edges to the first named strips, are placed edge-wise vertically, one between each two, the connection being so arranged that the tops of the arches do not rise quite as high as the tops of the first set of bars. Narrower strips are also arranged across and riveted to the lower flanges at suitable intervals apart, to serve as laths for holding the ceiling plastering to be applied to them, as well as to brace them laterally. Similar strips are arranged across and riveted to the upper flanges, or wood pieces may be bolted on to receive and support the floor boards. The outside flanges are built into and rest in the wall, and other flanges may be applied, if desired, to the outside strip for letting into the wall. For a floor of great length the bars are lapped and riveted.

NEW AND WIDE USE FOR INFUSORIAL EARTH.—The use of infusorial earth as a non-conductor of heat is suggested by the *Monetary and Mining Gazette*. Tripolite or infusorial earth, being a worse conductor of heat than coal ash, and almost as poor as flax chaff, and being refractory, is adapted for uses of ice cellars and fire proof safes, for casing steam boilers and pipes, etc., and possesses the advantage of affording protection against rats and mice. Its lightness is also a great recommendation. One cubic foot of it weighs 21½ to 26 pounds; the same bulk of dry coal ashes, 40½ to 42½ pounds. And of dry earth, 94 to 128 pounds. For casing steam pipes it is mixed with dry flax seed.

Infusorial earth occurs in inexhaustible quantities on this coast. It is largely used here for polishing powder as well as for other purposes. It is also largely employed in the manufacture of giant powder, although that obtained here is not considered sufficiently fine for that purpose—a better quality is imported from Europe.

COATING IRON WITH COPPER.—A German paper, *Deut. Illust. Zeitung* gives the following with regard to a method of coating iron with copper, so as to protect the former from the action of sea water and the like. The iron is cleaned and rendered perfectly bright by means of acid, and then immersed in a bath of melted copper, which is maintained at a very high temperature, so that it not only covers the iron but becomes incorporated with it. Iron coated in this way can be hammered and rolled without the copper tearing or peeling off. Specimens left in contact with sea water for nine months was unattacked and could be hammered and rolled out like new metal. Iron plates covered with copper in this way have two advantages over pure copper plates, namely, they cost less and are harder and stronger. There is also a great advantage in using coppered iron wire for telegraph lines, instead of galvanized iron.

THE FUTURE OF THE IRON TRADE.—The annual consumption of iron throughout the world has more than doubled within the last eighteen years—increasing from 7,000,000 tons in 1856 to 15,000,000 in 1874—and the average annual increase is greater now than ever before. England has hitherto been able to furnish one-half this supply, but as her resources are taxed to the utmost to keep up with the present demand, it is evident that the world must begin to look elsewhere for the surplus to meet the inevitable rate of progress in the demand for this great staple of industry. This will undoubtedly be America's opportunity, and hence we may look for a rapid and enormous increase in the iron industry of this country within the next ten years. The present annual increase in the demand for pig iron is not far from 800,000 tons.

PRODUCING A BROWN COLOR ON IRON.—Dr. Sauerwein recommends the following for producing a brown color on iron: The vessels to be covered are moistened with dilute nitric acid and allowed to dry, when the iron becomes covered with rust. This operation is repeated until the oxide film acquires the desired appearance. The vessel is then diligently rubbed with linseed oil varnish. The articles then possess a beautiful brown color, and are protected from further oxidation. Equally good results are obtained, but in another color, by dissolving two parts sesquichloride of iron, two parts butter of antimony, and one part gallic acid, dissolved in the least possible quantity of water, and rubbing the vessel with it. The operation may be repeated as often as desired, and then rubbed with linseed varnish.

GALVANO IRON WIRE A SILVER WHITE APPEARANCE.—This process has been devised by Dr. Heeren. The iron wire is first placed in hydrochloric acid, in which is suspended a piece of zinc. It is afterward placed in contact with a strip of zinc, a bath of two parts tartaric acid dissolved in 100 parts of water, to which is added three parts tin salt and three parts soda. The wire remains about two hours in the bath and is then made bright by polishing or drawing through a drawing iron. By this galvanic tinning wire which has been wound in a spiral, or iron of other shape, can be made white, which is an advantage over other methods, where the wire is tinned in the ore, and drawn through a drawing plate.

MOLECULAR CHANGE IN IRON.—It is generally, though not universally believed that the texture of wrought iron passes from a fibrous to a crystalline state when subjected to a long series of concessions. It is quite certain, however, that a similar change takes place, on the surface at least, when fibrous wrought iron is heated and then suddenly cooled. Professor Kick heated some of the best boiler plate in a muffle furnace, almost but not quite to a red heat, and then chilled it. On breaking, it was found that the outside portions were crystalline to a thickness of one millimeter. With thin plates this would produce great weakness.

COATING IRON WITH BRASS.—The following is given as a method of covering iron wire with brass, without the use of a battery. The process is a very simple one, and consists first in placing the clean bright wire in a solution of sulphate of copper, when it immediately becomes covered with a thin film of copper. It is then covered with a paste of pure oxide of tin, and heated to a temperature high enough to fuse the copper. Care must, of course, be taken to prevent the volatilization of the tin.

The Late Storm.

The farmers, not to be outdone by the miners have had their "honzanz" within the past few weeks, in the shape of a most abundant rainfall. It was thought at one time that the present would be a dry year for both miner and farmer, because such a long spell of dry weather followed the first rain of the season. Within the past two weeks, however, an abundance of rain has fallen; and the only trouble has been that it was more than was wanted in some localities. The late storms have been very general, extending all over this State, and a long way outside our borders.

In those places which were subject to floods, as at Marysville and some of the tule lands, they have had more water than they wanted. Sonoma county, too, which comes out best in dry years, could have done with less rain. All the islands in the delta of Sacramento county are more or less under water, except Grand Island, the most northern. The great Parks levee in Sutter county, inclosing some 120,000 acres of land, and which was made at a heavy cost, gave way. On these lands, however, a flood does not prevent a crop from being raised.

To the farmers in the great San Joaquin valley, this storm has been truly a God-send. They needed rain badly, and have got all they wanted. Their fears of a dry year are dispelled, and the faces of the farmers are wreathed with smiles.

Some of the mountain streams have done considerable local damage by overflow, and in some places were higher than during the great flood of 1861-62, carrying away debris left on the banks in the "wet winter." Some idea of the rapidity with which these mountain streams swell, may be derived from the statement of the Calaveras Chronicle, that the Calaveras rose seven and one-half feet in one hour and thirteen minutes.

In California the principal damage done was at Marysville and Yuba City, which were overflowed. In Nevada and Utah many lives have been lost by snow slide, and considerable damage done to property also. In Oregon three lives have been lost by snow slides.

Since the heavy rains we have had a severe northern blowing, which was predicted by the Signal Service Bureau. "Old Probabilities" were successful in this prediction, and saved considerable property thereby. As it was, however, a number of schooners were sunk at the wharves, and several vessels damaged by collision and churning. Some of the ferries were not running part of Monday, but by that afternoon the wind had died away. The vessels which postponed sailing by the advice of the Signal Bureau have since gone to sea. The north wind has had a very powerful drying tendency as usual, and our streets are already free from mud. The predictions of the Signal Service, telegraphed from Washington, were verified in a few hours, and afford another practical proof of the value of scientific meteorological observations.

Mining Stocks.

The bottom dropped out of the Stock market and prices of all descriptions went tumbling down farther than they ever went up. The heaviest declines are apparent, of course, in the leading stocks, but the smaller ones followed enit and went to smash with the larger. Of course it was only a question of time when this collapse would occur, for while several of the mines were selling at high figures on their merits, others were only buoyed up by the natural strength of the market. There is no diminution in the prospects of the honanza mines, according to the Virginia papers, and they will probably recover somewhat in price, though it is questionable if they ever rise as high as they were during the late excitement. Reference to our Mining Summary will give our readers an idea of the situation at the mines, and a glance at our Stock tables will show the decline in the values of the stocks. By comparing the prices of last week and those of this, a good idea will be had of the shrinkage in values.

WE ARE informed that a discovery of quicksilver was made about two weeks since, on the land of Hon. J. Mc. Shafter, occupied by Mr. Charles V. Payne. It is said to be a large, well defined vein, and the surrounding indicate that the metal exists there in large quantities. Mr. Payne has secured a report, and will immediately ascertain more about it.—*Marin Journal.*

THEY now want to abolish the office of State mineralogist in Nevada.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington, D. C., Jan. 26th, 1875.

FOR WEEK ENDING JAN. 12TH, 1875.*

BLIND SLAT ADJUSTER.—David Aaron, Marysville, Cal.

SIGHT FOR FIRE ARMS.—Thomas Dunstone, Santa Cruz, Cal.

WATER WHEEL.—Samuel W. Knight, Sutter Creek, Cal.

CHIMNEY GUARD.—Robert Priseman, Sacramento, Cal.

BLIND STOP.—Alford T. Eford, Oakland, Cal.

STONE CUTTING MACHINE.—Louis Dntertre, S. F., Cal.

BIRD CAGE ATTACHMENT.—George Fliedner, Portland, Oregon.

*The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest time possible.

A DAILY line of stage will soon be placed on the route between Indian Wells and Panamint.

General News Items.

A CLOSE CALL.—At T. W. Haskins' shingle mill, Pescadero creek, on the 16th inst., Wm. Milliken, while employed in lacing a belt, had his coat caught by a pulley, which wound the garment up in an instant, and Mr. Milliken found himself turning one hundred revolutions per minute, or less. Mr. Haskins, who was working near by, ran and grabbed the flying man by the foot, jerking him loose in a little less than no time. When the man of wonderful velocity viewed himself he found that his condition was one of nudity, excepting pants and boots; many bruises, but no bones broken. Had the coat been of strong material, there would be a dead Milliken, in all probability.

DANGER FEARED.—It is feared that danger may arise if the proposed dam is constructed on Calaveras creek, Santa Clara county. It is proposed to form a reservoir to supply San Francisco with water by erecting a dam 225 feet high, which will flood an area of 225 square miles, provided the reservoir ever became filled. Such a body of water thus reserved would be a constantly threatening danger to all and everything below; but there is no probability of such a dam being constructed. In expectation of it, however, land to be flooded has risen from \$40 to \$100 per acre.

A VALUABLE BRICK.—In the Bank of France they have got a brick for which they paid 1,000 francs in specie. It was taken from the ruins of a burned house, and the image and figures of a note for 1,000 francs are burned on the surface, transferred by the heat from a real note. This brick the bank redeemed on presentation, as if it were the note itself.

PENSIONERS.—There are 54 widows of Generals and 217 of Colonels on the pension rolls. When the pension paid the Brigadier-Generals, \$50 a month, was offered to the widow of General Maude, she very emphatically declined to receive it, because it was less than that paid Mrs. President Lincoln.

A BLACK DAY.—The revelations of the P. S. Co., Investigating Committee have marked up a black day for the American Congress, and, what has heretofore been considered the respectable press of the Union. The lamest duck just now is ex-Congressional Postmaster and Congressman-elect King. He has gone where the woodbine twined.

ALVISO RAILROAD.—This narrow gauge project is again advocated by the San Jose papers; but nobody moves. The company which was formed two years ago, got the right of way and stopped. Somehow it is easier to locate the road on paper than build it and decide on its management. Capital, for some reason, is offish.

ROOVERTING.—Gen. Cobb, of Alameda, who was shot on Washington street in this city a short time ago, by a woman, has so far recovered that he will be able to attend to business in a few days. The hall

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR COUNTY.

ASBESTOS.—Amador Ledger, Jan. 23: C. D. Horn brought to this office a few days ago some very fine specimens of asbestos, taken from a vein recently discovered northeast of Aqueduct city in this county. The vein appears to be narrow at the surface, but may increase downward. The fibers of the mineral before us are very fine, and we should judge from appearances that the article is of excellent quality. The claimants, Mr. Horn and F. M. Brown, intend sinking on the vein to ascertain its extent.

THE ONEIDA MINE.—Under the efficient management of the present superintendent, the above mine is presenting a very flattering appearance. New and substantial hoisting works have just been completed. The new shaft has reached the depth of 1,000 feet, and the mine thoroughly proven to the lowest level. The chimney increases as a greater depths are reached, and at this time presents an unbroken ledge of rich pay ore 500 feet in length. The rock now being taken from the mine, will average \$20 per ton, with enough developed to supply the mill with 100 tons daily for the next two years. The Oneida mine may be ranked as one of the most valuable mines in the county, and from this time on, its returns cannot fail in giving satisfaction to its owners. The present superintendent is not only the right man in the right place, but deserves much credit for the mining knowledge he has displayed in his management of the mine.

THE CALVERAS CITIZEN learns that the bed of coal recently discovered near Lancha Plana, in Amador county, is proving to be of excellent quality. The main shaft is now down to a depth of over 80 feet.

CALVERAS COUNTY.

MINING ITEMS.—Calaveras Chronicle, Jan. 23: A rich deposit of quartz has been struck thirty feet down from the top, which pays from \$60 to \$65 per ton, and the ore is getting better as we go down. The casing pay from \$20 to \$30 per ton. The lode is from fifteen to eighteen inches in width, and is growing wider. It is now by miners as a cross-vein, running north and south, which scientific miners say is better than east and west veins. The lode is situated two and a half miles north of Vallecito, in the head of what is known as Helleye gulch. The claim was formerly known as the Greaser lode, but has since been changed to the Queen of the West. The mine is owned by Hensch & Wene, of Copperopolis, who intend to erect a small mill next spring.

PRINCE has been commenced in the Red Hill hydraulic claim, and operations are to be vigorously pressed from this time forward. A 10-inch iron pipe conveys water from the ditch to the mine, giving a pressure of about 180 feet. In addition to the Red Hill claim proper, there is a good deal of surface ground adjacent that will pay well for washing.

The work of sinking a shaft from the lower tunnel of the San Bruno mine, at Mosquito, is progressing favorably. A sufficient quantity of water has not yet been struck to necessitate the use of the engine and hoisting works. The rock obtained from the shaft is exceedingly rich.

SHUT DOWN.—Calaveras Citizen, Jan. 23: The Anderson Flat mine stopped working last week; the object, we understand, is to enable the company to put up smelting and reduction works, as the ore is inclined to be refractory.

ENTERPRISE.—The new eight-stamp mill works admirably, and the energetic superintendent, Fred Morris, wears a bland smile indicative of an assured satisfaction as to the success of his enterprise.

MILLING.—Henry & Son commenced running their mill on the 13th inst., crushing rock taken from the Madra, of which they are the owners. They will do custom work when the mill is not employed in crushing ore from the Madra.

EL DORADO COUNTY.

MINES.—Placerville Republican, Jan. 21: Peter Gross, after having twice almost effected sale of his mine in Big Canyon, near this city—recent negotiations having been cut short, as the arrangement were about completed, by the sudden death of the principal purchaser—has determined to keep and work it himself, and has purchased a ten-stamp mill for that purpose, and now has most of the machinery on the ground. From the North side we receive flattering reports from both the Taylor and Woodside. Reports from the latter represent that they have struck a five foot ledge which is very rich, and has every appearance of being permanent.

HUMBOLDT COUNTY.

CINNABAR.—Humboldt Times: It is now conceded that discoveries of cinabar lodes have been made in this county. Specimens of the ore have been tested with satisfactory results. The locality of the discoveries is in the vicinity of the Kneeland's Prairie and Round Valley wagon road, and near the boundary line between Humboldt and Trinity counties. Two unred persons are reported as being on the ground locating claims.

NYO COUNTY.

RICH STRIKES AT PANAMINT.—Panamint

News, Jan. 23: We hear of rich strikes in several mines here, made in the last day or two, which have not heretofore occupied much of the public attention, and also of very rich ore in one or two prominent mines much beyond the expectation of the owners.

OUR MINES.—From Capt. Messic, the energetic and competent superintendent of the Surprise Valley mill and water company, we learn the following in regard to a few of the most prominent mines of this company now being worked. His statements are corroborated by those of others, who are not in any way interested in these mines or the business affairs of the company, and who, from scientific knowledge and practical experience, are competent to judge of the value of ores and proper method of working mines.

JACOBS' WONDER.—The main tunnel, running east from Big Canyon, is in splendid ore and looking better than ever. A general improvement is noticeable in all the different openings. In fact, the prospects exceed the expectations of the most sanguine when work was first begun on this mine.

WYOMING.—This mine, in which a vein of black ore was struck two or three weeks ago—assays from which went as high as \$12,820 per ton—is still looking as well as usual, and a large amount of very fine ore is daily being taken out.

HEMLOCK.—The shaft in this splendid mine has cut the ledge at a depth of about 115 feet, which has developed a large, fine body of ore. The shaft being vertical, and the ledge heaving but little pitch, it is difficult to tell how wide this ore vein is until the foot-wall shall have been reached.

STAMP MILLS.—The company are pushing ahead with grading and getting out timber for their mills—the one at the head of the canyon will be a twenty-stamp mill, with a capacity for ten stamps more, while the mill lower down the canyon will be larger, not less than thirty, and probably of forty stamps. The departure of Mr. Henry A. Jones, last Saturday, for Spedra, was for the purpose of hurrying forward the machinery for the mill at the head of the canyon.

BENTON.—Cor. Inyo Independent, Jan: The mines are looking splendidly, and producing ore that will mill from \$250 to \$400 per ton. There is, however, but little ore now being taken out by parties not having facilities for crushing, as it is difficult to get any of our mill men to work ore for individuals or small companies. Per consequence, it is very discouraging to prospectors. A small custom mill would be a paying investment; besides, it would assist more in the development of the mines, and be better for us generally than for a company of any reasonable amount of capital to invest here, unless they should make the working of custom ore a specialty. Madam Rimmer says that Mr. Wetherill has sold his mill and mine to a party Virginia, and that the new proprietors are going to erect extensive reduction works. Pat Forey has sold to J. A. Creaser a one-third interest in the St. Louis mine.

KERN COUNTY.

COSO DISTRICT.—Kern County Courier: Messrs Colby, Jewett and Brundage bring favorable news from New Coso. Several hundred men are on the ground and new discoveries are constantly being made. About two miles from the first locations some leads of milling ore have been found similar to those of Panamint. The specimens shown us by Mr. Brundage look quite as well as any ore we have seen from that place. Judge Colby brought a sack of ore from the Defiance, the lead owned by himself and P. Reddy. Those familiar with the ores of the celebrated Union mine at Cerro Gordo say it is impossible to distinguish it from ore of that mine. The formation in which this mine is found is precisely similar, but is more favorably situated for work and vastly larger. The measurements of the U. S. Deputy Mineral Surveyor give it a width of 196 feet. A cut or tunnel is now being run across it with a view to better ascertain the solidity and continuity of the vein and character of the ore. A town is being built contiguous to the mines, called Darwin. A hotel conducted by Mr. V. G. Thompson is already in operation. Water will be supplied by means of pipes laid from springs, six miles distant from which the grade is downward. As the leads here are richer, larger and more numerous and easily worked than at Panamint, a still greater excitement is sure to spring up. The galena ores may be worked far cheaper than the milling, and the necessary preliminary outlay is not half as much. But it is too early yet for men of prudence to visit this promising locality. The weather, for two months, to come, will continue uncomfortably cold in that quarter. We may expect lively times there this summer.

NAPA COUNTY.

CALISTOGA ITEM.—Calistoga Free Press, Jan. 23: Three tons and a half of ore from the Georgia mine worked in the Missouri retorts yielded seven flasks of metal.

The hydraulic works at the Yellow Jacket are in full operation. Five hundred feet of new sluice boxes are being erected.

The Kellogg furnace at the Knights valley ranch is working tons of ore for the Oakland mine to test the value of the ore.

Recent work on the Mercury adjoining the Geyser shows fine metal, and the appearances of the mine will warrant the erection of a furnace as soon as the weather will permit.

The first cleanings of the Geyser furnace will take place the first of next week. The mine is developing finely, and the quantity of

ore available for the furnace is daily increasing. Sluicing at the Gravel mine, Pine Flat, is progressing finely. The ore gathered in the boxes is very rich, and will be run through the Ida Clayton furnace as soon as it can be hauled.

The Steele tunnel at the Ida Clayton is in 180 feet, and drifts are being run both north and south along the wall of the ledge, ore being taken from both drifts. The Laird tunnel is in 190 feet, and when finished will be 1,180 feet long, and tap the ledge 387 feet from the surface.

Fifty-four flasks of quicksilver were shipped last week by the California Borax Company to Parrott & Co., San Francisco. Eighty-four flasks from the Great Western Quicksilver mine to Virginia, Nevada.

NEVADA COUNTY.

RICH GRAVEL.—Nevada Transcript, Jan. 23: We learn that very rich gravel is being found in the Manzanita mine. The amount we hear a pan prospect is so fabulous, that we refrain from giving the report. We hope to be able to give an authentic report soon.

OMEGA WATER AND MINING COMPANY.—This mine, situated at Omega, in the upper part of the county, is running to its fullest capacity. The company use about 2,200 inches of water in four pipes. Two pipes only were used from the first of November, and were continued for forty-five days, when a scarcity of water compelled shutting them off. There has been nearly a month's run since the late rains. The pipes are now so arranged that there is a much greater fall, and as a consequence an increased amount of dirt is washed daily. Last year this mine paid dividends. This year, with the increased facilities for washing, their profits will be nearly doubled. There is no better mine in the county. The ground is extensive; is rich with gold, and the company own the water used. We should not object to a few shares in it.

THE PLAZA QUARTZ MILL.—The above mill, owned by Jones & Keith, is kept busy most of the time in crushing prospect rock. On Saturday it was running on some rock taken out of a ledge up on Deer Creek, owned by Mr. Erskine, and the plates showed a very good prospect. The roads are now in such a condition that it is difficult to draw an empty wagon off the unheated track, so there will be but little done at the mill for awhile.

PLACER COUNTY.

RATTLESNAKE BAR.—Cor. Placer Argus, Jan. 23: I am happy to be able to report more favorably of our mines than formerly. The Cray Brothers claim is paying exceedingly well, they have struck splendid paying gravel. They really deserve good pay as they have been to over \$2,000 expense on the claim during the last year. They have a splendid apparatus, and are driving the work day and night. It is astonishing to see the large rocks the Little Giant drives into the sluices.

B. W. Houseworth & Co., are also doing good business with their Giant since the rein Other parties are also preparing to wash soon, which looks more favorable for our place.

SAN BERNARDINO COUNTY.

BEAR VALLEY.—Santa Barbara Press, Jan. 16: This rich mining district is attracting the attention of miners and capitalists, and promises that the anticipations of those who predicted a bright future will be more than realized. The 40-stamp mill which is being constructed, will be completed in a few weeks, and furnish employment for several hundred men, besides demonstrating the wealth of that district which is as yet little known. The Panemint and Coso excitement has caused but few to abandon Bear Valley, so great is the confidence which miners have in the district. There will soon be a mail line established from San Bernardino to Holcomb Valley, which is only four miles from Bear Valley. A great advantage which that district has over many others is the great abundance of wood and water contiguous to the mines. Lumber is abundant and cheap, the climate so mild that work is rarely interrupted during the winter, and a more healthy locality cannot be found in any of our mountains.

SAN DIEGO COUNTY.

JULIAN AND BANNER DISTRICTS.—Cor. San Diego World: It is reported in town that the Cheriot mine has struck an immense volume of water in their shaft.

The Reedy Relief is running steadily day and night on good ore. The shaft in the Owen's mine being pushed rapidly.

The Kentuck and several other mines in the section are looking well. The Antelope mine changed hands a few days since. The Antelope has been a good mine, and no doubt with proper management will prove remunerative to its owner.

SIERRA COUNTY.

FOREST CITY.—Mountain Messenger, Jan. 23: Advice from Forest City are to the effect that the North and South Forks were exceedingly high on Tuesday. The lower bridge, on the road leading to Pike City, just below the junction of the two forks, was carried away. We also learn that quite a number of the boxes of the Bald Mountain Company's sluices were carried off. Whether they were near the head or foot of the flume, we did not learn.

The new company, which recently purchased the Pioneer claims, have already received a portion of their freight, and will at once commence getting ready to open them. They will work a Burleigh drill.

THE STORM.—On Tuesday last we were visited by the highest water this section has known since the remarkably wet winter of 1861

and 1862, the water rising to within a foot of high water mark of that winter. It is claimed by some that the water would have been full as high as then had not for the changed condition of the river bed, it being then full of tailings of which it was before this storm remarkably clear, owing to comparatively little river and bank mining done of late years. The water commenced rising rapidly Monday night, and Tuesday morning both rivers which form a junction here were hanks full, the North Fork being the highest, owing to its comparative shortness.

The mining pipe and hose of Shaffer & Garibaldi, on the hillside north of town, were filled up solid with sand, and one of their ditches filled up and the other cut away, so that this storm will do them no good, besides damaging them to a considerable extent otherwise.

Some of the pipe of the Green Mountain Company is reported to be seen at the mouth of Sling osden. We believe they have not yet found their "monitor." This is a rough deal for the boys.

TUOLUMNE COUNTY.

GOLDEN GATE.—Tuolumne Independent, Jan. 22: The Golden Gate mine looks better than ever since being opened. They have come upon a large body of rich sulphuret ore which goes \$1,600 per ton. The mill saves about 20 buckets per day, weighing 50 pounds each, making one-half ton besides free gold.

THE MARKS & DARROW is going ahead very fast in sinking their shaft, in consequence miners are opening their eyes, and locating and re-locating in the vicinity with intent to work the same systematically.

THE ALABAMA.—This mine is near the Rawhide, abutting Table mountain, and was owned and worked to a profit four years ago by a man named Reese. He was killed, and the mine has remained idle until lately, when it passed into the hands of a San Francisco company, and work has now commenced to properly develop the property, with very encouraging indications. An open cut has been run along the vein, and sinking has commenced. The pay shaft is 300 feet long and 100 feet wide, full of rich threads, and the object is to sink down and find the point of concentration. A new water wheel is being constructed and the mill is being re-erected. The mine has always paid expenses and over, and when system and skill is applied, and depth attained, the Alabama will take a high position. Mr. Douglas Browne is Superintendent, and is fully alive to the interests of the company, being opposed to erecting costly improvements until he is thoroughly satisfied the mine will justify the outlay. He is right. Economy and skill should go hand in hand in developing a mine. The reverse system has done more injury to the quartz mining interest of this county than all other causes combined. The value of our most prominent mines of to-day has been proved and their reputation established, by Superintendents who have adopted the system indicated, and who have a desire rather to manage their mines as scientific and business men, than to create an excitement by making a splurge and wasting the means of stockholders in a sham "energy" which leads to ruin and abandonment of valuable property.

Nevada.

WASHOE DISTRICT.

SIERRA NEVADA.—Gold Hill News, Jan. 21: Sinking the new shaft is making good headway, the rock in the bottom blasting out finely. The flow of water is gradually decreasing, and the pump now handles it with ease.

DAYTON.—The ore in the face of the main south drift at the third station level is showing a decided improvement. The south drift on the second level is also improving. The ore breasts are all looking well and yielding the usual amount of good milling ore.

CHOLLAR-POTOG.—The heavy snows having stopped the hauling of ore to the mills, the dumps have all been filled and the extraction of ore suspended until the roads are again cleared.

UTAH.—The face of the south cross-cut, on the 400-ft level, is still in a mixture of quartz, porphyry and clay of a very promising character.

CONS. VIRGINIA.—Daily yield, 420 tons of ore. The ore breasts on the 1200, 1300, 1400 and 1500-ft levels are all yielding splendidly. The ore breasts on the 1300 and 1400-ft levels are extended both north and south, and are of an increased richness. The ore body on the 1100-ft level, which has heretofore been neglected in the haste to prospect the ore developments downward, is now being opened out, and is proving much better than was expected. A large number of men are now employed in the development of that portion of the mine. Cross-cut No. 1, east, on the 1500-ft level, is in 350 feet, the face still in the richest quality of sulphuret and chloride ores. Cross-cut No. 2, on the California lode, is also in the same immensely rich ore. The face of the main north drift on the 1555-ft level, is still, if possible, richer ore than ever. This drift is now 50 feet into the California ground, having passed the entire distance through a solid body of rich sulphuret ore, intermixed with stephanite and native silver. The east cross-cut from this drift 200 feet south of the north line is still pushed vigorously ahead, the face still in the same magnificently rich ore as that found on the levels above. The new mill is running steadily on ore from the mine, and every new prospecting drift run seems only to increase the already fabulous amount of wealth developed.

The Richmond Mine.

A Large Body of Ore.

It is generally known that during the administration of the present managing director of the Richmond mining company, at Eureka, no visitors were allowed access to the mine, and although rumors of important strikes and rich discoveries have at times been circulated, no positive evidence as to the truth could be given, as the rules concerning visitors were rigidly enforced. At the last annual meeting of the directors of the company, the chairman, in the course of his remarks, gave a description of the progress made in the mine, which for the benefit of our readers, we reproduce from the *London Mining World*:

When the present managing director first arrived at the works, in June last, he found that the works of exploration had been most unaccountably stopped; that they had been driving on in a straight line, through a body of very poor ore without testing it, right or left, as usually had been done. It so happened, for the second or third time in the history of the mine, that the lode, which usually dipped at about an angle of 60 degrees, had lifted itself up and gone horizontally. They drove through this horizontal stratum of iron ore and found it too poor to work; it was practically of little value, and it was supposed by some that we had come to the end of the Richmond mine; that we had run into valueless stuff, and should not find any more worth taking away. We had met with just the same accident before—that is, the lode had lifted horizontally and been running partially through this iron ore, which frequently accompanies ore like ours.

As soon as Mr. Probert took charge of the mine, drifts were run in, above and below, sideways and underways, and immediately rich bodies of ore at the left and above were struck. The poor ore had given rise to a rumor of collapse, instead of which we had found a large body of good ore, forty feet thick, extending over the whole of it.

Sinking on the lode began immediately; it resumed its normal dip, and as the sinking progressed the pipe of ore increased in width. The very mass of ore which was supposed to be so poor contained, at a rough estimate, 100,000 tons from which deducting the iron portion, leaves 60,000 tons, which is held as a reserve. At one point, before reaching this low level, thin streaks of ore had been observed coming in. This was another promising feature, and a force of men were put on to explore the spot. In less than three weeks the developments extended down 50 feet. Beginning in narrow streaks, at 70 feet they opened out in a ledge 16 feet in width, and at last accounts the developments were being continued with the most satisfactory results, carrying the same breast of ore, and from which is being daily taken out 40 tons of splendid carbonates.

The continuation of the exploratory works were commenced right and left, further discoveries were made and the language of the Superintendent best expresses the extent of the vast ore body: "There is ore in every direction I come to." At the bottom of the great hoisting shaft, which was sunk a long way beyond the inclines, a drift of one hundred feet had been run, and in sinking a winze 50 feet down a body of ore was struck which was thought to be too good to be in the Richmond lode. A splendid lot of carbonates was opened; at the depth of 70 feet the ledge was 30 feet wide, and they have raised upon it and it is forty feet above, and there they still find it; and the last report from the managing director is to the effect that it is unquestionably the Richmond lode, discovered 300 or 400 feet beyond the point at which it had previously been traced down. The ores at this depth assays \$100 a ton and proves the correctness of the theory, that as a mine gains in depth it increases in richness.

The chairman of the meeting stated that the full information in regard to the mine would not be published for the reason that it was not deemed advisable to do so, or to let the exact direction of the works be known to the public, because it must have to be known to the other side, in which case there might be trouble with "jumpers" who might have gone ahead of the company, and if they had not got positive indications might have attempted to anticipate.

EXCEEDINGLY RICH.—The new mill of the Consolidated Virginia company is now running on ore from the bonanza. The ore is working kindly and is proving immensely rich. Where a change of pulp is placed in the pans the quicksilver at once begins to thicken with the silver it is taking up. The richness of the ore necessitates very frequent straining of the quicksilver. Only a portion of the mill is running as yet, but it is already seen that the facilities for retorting the amalgam must be enlarged fully two thirds when the whole mill goes into operation. Millmen who have been watching the working of the ore say that it is going to pay at the rate of \$300 per ton.—*Enterprise*.

The hydraulic works at the Yellow Jacket quicksilver mines are in full operation. Mr. Stuart is superintending the matter in person. The dirt is washed by means of an immense pressure and a "Little Giant" into a ground sluice, and from thence through rifle boxes. Mr. Cross, the local superintendent, confidently expects to concentrate the fine cinabar to an average of two per cent.

The Denver smelting works, Colorado, are for sale.

Miners' Chances.

The *Virginia Chronicle* says: "If absence of care is happiness the population of Virginia City ought to be the happiest in the world. There is a feeling of indispensance here scarcely ever experienced elsewhere, and a freedom from the artificial trammels of society which in older communities are based on wealth, birth and position. In other words, every man is a man in his boots. Many of the miners are worth from \$5,000 to \$50,000, and work for occupation rather than from necessity. When they are engaged in a mine, they are always on the lookout for developments, of which they are quick to take advantage. They have friends in other mines with whom they compare notes, and they often in this manner succeed in accumulating large fortunes. The recent discoveries at the north end of the Comstock were known to the miners long before the public were made acquainted with the existence of the bonanza, and many of them realized handsomely from the rise in stock. In most other communities a working man has no means of getting rich, except from the proceeds of his own labor. It is a dead open and shut with him, and a fortune is so difficult to acquire that an undue respect is paid to the possessor of money. Here everybody is a speculator, in fact. There are but few who do not own stock in some mine, which they hope will turn out well, and they do not know what moving they may get up and find themselves rich. Their daily labor is very well as far as it goes, but the ground upon which they base their expectations is their stocks. The late developments, and the assured prosperity of the country for years to come, with the hope of new discoveries, has strengthened this feeling, and it is hard to find anywhere a more hopeful, sanguine and independent population than that of Virginia City."

COLORADO GRAVEL MINES.—The Canyon City (Col) *Times* learn that extensive plans are being laid for systematic mining in California gulch the coming season. The Oro ditch and mining company have completed a large ditch from the Arkansas river to Iowa and California gulches, and a large force of men will be put on in the spring. A Mr. Wells has constructed a ditch from which water can be obtained for working the immense gravel deposit on the summit of Printer Boy mountain. The *Times'* account adds that upwards of a ton of gold has already been extracted from the Printer Boy lode, and appearances indicate an increasing yield in the future.

THE GOLD HILL CHASM.—The crack or fissure in the ground situated a short distance east of Gold Hill is still opening out laterally and longitudinally. Starting from a point a short distance north of Fort Homestead it has already extended a distance of half a mile in a southeasterly direction. The ground on the west side of the fissure has settled about two feet. The phenomenon is accounted for in various ways, some being under the impression that the ground in that locality has cracked open from being undermined, others claim that the chasm was occasioned by an earthquake.—*Virginia Enterprise*.

ISAAC LONG has shown the *Healdsburg Flag* specimens of bituminous coal from a deposit found on his farm, four miles and a half above Healdsburg. There are many narrow veins within a width of twenty-five feet, but the ground has not been prospected enough to indicate the extent of the deposit. The coal is of inferior quality, though it burns with a bright flame when put into a hot fire, and it may be the croppings of a valuable coal bed.

MILL AT TYBO.—From Mr. Trowbridge, who arrived in town last Saturday, we learn that the Tybo consolidated mining company has purchased the Highland 20-stamp mill, of Pioche. Part of the machinery is already on the ground and laborers are at work grading a site for the building. The company owns several mines which will yield nothing but milling ore, and about two thirds of the ore from the 2 G mine is of that character.—*Eureka Sentinel*.

ENGINES FOR THE RIVER MILLS.—In case of no snow falling in the Sierras this winter to furnish water for driving the mills on the Carson river, steam engines will be set up in them. For the largest among them, as the Eureka and others, condensing engines, similar to that now running in the big mill of the Consolidated Virginia company, will be used. It will be cheaper to put up engines here than to lose a single month's run of the mills.

MILL.—The Black Warrior mining company, near Wadsworth, are preparing for a mill, which they expect to erect on their mill site during the next sixty days. Considerable interest is felt by our Wadsworth friends in the Black Warrior mine, and six new claims have been located during the past week in that vicinity.—*Keno Journal*.

ROUGH ON THE AGENTS.—The Arizona *Miner* says: Show specimens of Arizona quartz to the heathens of New Jersey and other foreign countries, but don't, oh, don't show your ledge to an Indian agent, or he'll be sure to have it taken into a reservation.

A good deal of attention is attracted lately to the new mining camp called the Lewis district. It is thirteen miles, in a southerly direction, from Battle mountain.

Naval Machinists.

The following recent order from the Navy Department will probably be of interest to many of our readers:

NAVY DEPARTMENT.

WASHINGTON, November 17, 1874.

A candidate for the position of Machinist, Boiler maker, or Coppersmith, must not be less than twenty nor more than forty years of age. He must pass an examination in the presence of the Commanding Officer of the rendezvous, by at least one Naval Engineer, as to his qualifications as a Machinist, Boiler maker, or Coppersmith, and must also undergo the usual medical examination touching his physical fitness for the Naval service.

He must be able to read, and to write with sufficient correctness to keep the steam log of his watch. He must know the names of the various parts of a marine engine; understand the uses and management of the various gauges, cocks and valves; how to raise steam, start a marine engine, regulate its action and modify its action.

He must know how to ascertain the height and density of the water in the boilers, how to check foaming, and to guard against other danger from the boiler; how and when to regulate the quantity of the injection water, to guard against danger from water in the cylinders, and the measures to be taken in the event of a journal becoming heated; and, in short, how to act upon the occurrence of any of the ordinary casualties of the engine room.

He must understand how to do the ordinary overhauling and repairing of steam machinery, the packing of the various joints and rods, the grinding in of valves, putting on hard and soft patches, taking out, putting in and plugging tubes, and all other similar work required in the management of marine steam engines.

The monthly pay of a Machinist will be \$75; of a Boiler maker, \$40; and of a Coppersmith, \$40; besides the usual ration, and exclusive of the \$1.50 per month added to the pay of all enlisted men by the President's order of July 1, 1870.

Five machinists will be allowed to first rates, and four to second and third rate steamships in commission for sea service.

Boiler makers and coppersmiths will not be examined, except as to their qualifications as boiler makers and coppersmiths.

One boiler maker and one coppersmith, if obtainable, will be allowed to each first, second and third rate steamships in commission for sea service. They will be required to keep watch in the engine-room or fire-room while the ship is steaming, and at other times, as may be requisite, and will thus be enabled to make themselves proficient for the rate of machinists.

Machinists, coppersmiths and boiler makers will mess with the master-at-arms.

GEORGE M. ROBESON, Secretary of the Navy.

The South Yuba canal company, says the Nevada *Transcript*, are running a tunnel, about 1,200 feet long, under the hill beyond the Manzanita mine, for the purpose of conveying the water of the Snow mountain ditch through it to the town and adjacent mines. The work was considered necessary from the fact that the Manzanita company have washed away the hill nearly up to where the present ditch runs, and there is a liability of there being a cave which will carry away the ditch at any time, and shut off, not only the mine, but the town from water. The tunnel is eight feet wide and six feet high. Men are at work on both ends, and they have about 650 feet completed. The tunnel was commenced in October, and will be completed in about two months more.

The Inyo *Independent* learns that the Cerro Gordo Water company's pipes have burst, from the effects of frost. In consequence of this misfortune the furnace will have to be shut down for a short time, if not for the remainder of the winter. Since the accident, water for domestic purposes is being packed in upon pack animals.

ARRANGEMENTS have been made by the company recently organized at Winnemucca to work the Antelope and Mountain Sheep ledges, in Piute Queen district. An outfit will start for the mines, with tools and provisions, as soon as the weather will permit.

The South mountain people are making preparations to smelt and ship 30,000 pounds of bullion daily, next spring and summer. They have the ore to do it with in sight, and are putting up more furnaces.

The men in the Savage mine have made up a purse of \$385 for the widow of John Kelly, killed in the mine last month.

POTTER valley, Mendocino county, is having its share of mining excitement. Prospecting for silver is lively.

The mines in Rye Patch are said to be looking better than ever, and the prospects for a flourishing season are extremely good.

FROM the 1st of January to the 1st of October, 1874, 1,624 miners, bound to Cassiar, landed at Fort Wrangle.

The Eureka furnaces have produced, in the last two weeks, 541,805 pounds of bullion.

The Ukiah mining district, Mendocino county, was organized on the 7th inst., S. Wertimberg was chosen Recorder.

Our Iron Mines and Lincoln Coal.

If iron can be freighted from Shasta county, coal from Lincoln and limestone from Auburn to Sacramento and then smelted, and pig iron produced at a cost of \$24 75 per ton as estimated by the *Post*, thus supplying this California market with this great staple at less than half the present rates—for it costs at least \$15 a ton to freight iron here from the East—all will agree that the gain to California will be great. Two and a half millions saved net, or five millions of a gross saving yearly to California industry is a desideratum devoutly to be sought. Now while we are hardly prepared to accept the figures of the *Post*, for they are based on assumed freight rates for Shasta ore and limestone, which we do not believe can be obtained, we do believe that a splendid article of pig iron can be laid on the shipping wharf at Sacramento for less than \$25 per ton.

In the first number of the *Tidings* issued a little over a year ago, we took occasion to call attention to our foot-hill iron ore deposits and made the assertion that by erecting furnaces at or near some of these great deposits, say those ten or fifteen miles below this town and near the Placer county line, pig iron could be made at a cost not to exceed \$20 per ton. This was before the discovery of the Lincoln coal fields and based on the use of charcoal. If Lincoln coal should prove as well adapted to smelting as it is now thought it will, pig iron may be turned out at the furnace for \$15 or less per ton.

It has been a favorite idea of ours ever since the discovery of Lincoln coal, and hence when we have published in reference thereto has generally been in the local department, that that coal field and our iron fields or deposits were destined some day to be brought together and produce astonishing results. If the two great crude products iron ore and coal, and the lesser one lime stone, should not be found more closely contiguous than they have already shown themselves in inexhaustible quantities along the lower line of our county and Lincoln—and they are not likely to be so far as can be judged by a glance at the lay of the land in California—rolled iron can be produced after nailing these two points by rail—always supposing this coal to be what is claimed for it, as good as charcoal for smelting and forging—cheaper than anywhere else on the coast, and perhaps in the world.

Figure the cost of a railroad from Lincoln to Bear river, then of smelting works at the upper and rolling mills at the lower end of this road—as it takes two tons of ore, two of coal and half a ton of limestone to make the ton of pig iron, the coal had better be taken to the ore and lime and load back with pigs; then place the cost of mining and delivering the ore and limestone in the furnace at \$2 per ton, and the cost of the coal in the ear at Lincoln at the same, and these rates will be borne out in practice if the furnace is put at the right point and see what the cost will be for rolled iron.—*Foot-hill Tidings*.

BLACK JACK.—A correspondent of the Salt Lake *Tribune* writing from Black canyon says: The developments in the camp have not been so extensive as they would have been, if we had any facilities for reducing our ores. The ores consist mostly of chlorides and sulphurets of silver, carrying some gold, and are classed among the best milling ores in the territory; and I assure you, that if some capitalists would erect a ten or twenty stamp mill, for octom work, in the vicinity of this camp, say, at or near the Jordan river, or at Sandy station, they would be amply rewarded for their enterprise, from the profits arising therefrom. It is to be hoped that some one in possession of means enough, will embrace the opportunity yet open, at an early day, and erect suitable machinery in the way of a stamp mill for the reduction of these ores, and when once accomplished, I unhesitatingly say, that this camp will furnish as much of the precious metals as any camp in Utah, and will encourage the opening of other mines which have been idle for some time.

NEVADA COAL MINES.—The *Virginia Chronicle* says: "The Virginia Coal Company, whose property is situated in El Dorado cañon, about eight miles from Dayton, are developing their mine as quickly as possible. They have a large bed of coal in sight, and are at present engaged in putting in cages, preparatory to taking it out for the market. A new superintendent, who is an old coal miner, and has had an enlarged experience, has been appointed. The company expect to commence furnishing coal in quantities to suit in a few weeks. It has been submitted to trial, and is found to be a splendid article of fuel for ordinary purposes. The bed is of sufficient extent to supply the demand in this city, and if the enterprise turns out as there is every reason to expect, the property will prove of great value to the owners."

WINNEMUCCA mountain is getting the most tremendous scratching these days that an old gray hill ever underwent. Prospecting parties are starting out from town every day, and hardly one comes in without reporting a good strike. Uncle John Robins and Bill Powers struck a twelve foot ledge Monday, full of some sort of mineral.—*Humboldt Register*.

The Fiske lode at Central, Colorado, yielded during the year 1874, in bullion, \$44,941.99. The product has increased from month to month. The yield of the first eight months was \$22,349.36. In November it was \$5,737.69, and in December, \$9,595.86.

GOOD HEALTH.

Consumption of the Lungs.

EDITORS PRESS:—The more important labor of revitalization of the blood, taking place in the lungs—if that organ be implicated—it is essential to recuperation that no unnecessary labor be given it. Therefore the air inhaled should be pure, and the food that is used, also; consequently but few localities are well adapted to the recovery of persons afflicted with any predisposition to diseases of the liver or lungs. Breathing being both mechanical and chemical in its operation, and the force required being a draft on the vitality, all methods must be contrived to husband that force. The first step is to place the sufferer in proper climatic surroundings, which should be an altitude of from 1,200 to 1,500 feet above sea level, with the temperature as near 70 degrees (Fahrenheit) as practicable. The hygrometer should indicate less than an average of moisture. These conditions attained, the next in importance is the food. Partial indigestion usually preceding, the stomach must be attended to. Most of the mistakes in nutriment begin in the mouth. To have digestion, thorough mastication is an absolute necessity, and the food must be selected with a view to compel the performance of that operation. Parched grain, or hard bread, made from the whole of the grain is good; vegetables and fruit next, as containing the required moisture.

The corrosive qualities of food differ widely in giving a stated or definite amount of power to the engineer, so with the food in the human locomotive, and hence it should be chosen with this fact in view. Those classes of foods which rapidly decompose when introduced into the stomach should be avoided. Among these are milk, beer, wine, etc. Grapes are excellent diet for the consumptive, as they contain all the elements required to form good limpid blood. This quantity of limpidity is as essential as a freedom from the excess of carbon in the blood, when it enters the lungs, thus lightening the labor of the weakened organ. The operation carried on may be likened to that of generating power in a furnace, the throat and lungs answering to the furnace; hence if there be a defect in the furnace the whole operation must be governed with a view to lessen the wear and tear until such time as the grate bars can be renewed. The custom of administering oils and alcoholic liquors in this class of diseases can only be likened to using coal oil or kerosene to extinguish a fire. By living in the open air, where that air is naturally pure and free from excessive moisture, by the use of electricity passed by moist sponges through the relaxed portions of the body; by the sun bath and by general cleanings, the disease can be arrested in nearly every stage—still much depends upon the skill of the manipulator. All that it is required to know to treat successfully this usually fatal malady can be gathered from the above.

R. M. SHAW,

Los Angeles, January 1, 1875.

IMPURITIES IN THE ATMOSPHERE.—Few persons are aware of the large amount of dust, fibrous substances, etc., that are constantly floating in the atmosphere, aside from the deleterious gases also present. The air which ventilates the English House of Parliament passes through filters of cotton. The appearance of the filters after having been used is startling, indeed; they are of a heavy, murky brown color, thick with dust and organic impurities. The sieves through which the air is first passed have also deposited near them quite a heap of larger intercepted particles. By allowing a sunbeam to enter a slightly darkened room, no matter how free we strive to keep it from dust, we shall always find the path of the beam illuminated with an infinitude of floating particles of organic matter. If we could see the impurities in the air we are constantly breathing as clearly as we see them in the path of a sunbeam through a darkened room, we should utterly revolt at being compelled to breathe such an atmosphere. The air of our various manufacturing and our machine shops, with the ventilation usually given them, is really unfit for a human being to take into his lungs. Careful examination has proved that the air in our railroad cars, as we go whirling along the track, is filled with invisible particles of iron and wood, to say nothing of other matters, to an extent which seems almost incredible. A better system of ventilation is one of the most important needs of the day.

THE HEAT OF THE BODY.—In olden times, when a physician wished to determine the character of a disease, he had to rely on his sense of touch to tell whether his patient was feverish or not; if the physician's hand was hot, then his patient felt but moderately warm; but, if it happened that his hand was cold, then a moderately warm patient seemed to be hot and feverish. This difficulty is now quite solved by the use of a thermometer. The heat of the human body is about 98 degrees Fahr., and, by placing under the armpit the bulb of one of these instruments, it is readily seen whether the temperature of the body is higher than that. It has been suggested that if mothers were to use the instrument, much anxiety might be saved, for, if it indicated a temperature higher than normal, then the medical man's aid might be very fitly sought, while, if it showed no excess, unnecessary fears would be allayed.

RISKS HIS LIFE ON HIS FAITH.—Professor White, a champion swimmer, recently consented to drown himself, in order that his theory of resuscitation might be tested for the benefit of the London Humane Society, who were present to witness the experiment. After lying down certain rules for holding a drowning person in the water, he plunged into the river—the Serpentine, probably in Hyde Park—and remained long enough under water to be partially drowned. His son then dived over him and brought him to the surface in an apparently lifeless condition, adhering strictly to the principles laid down by his parent. The breathless body was then turned over to one of the Humane Society's officers and put through the course of treatment recommended. The society had the satisfaction of seeing Mr. White revive, and in a short time return to the water without apparent unpleasant consequences, thus proving his theory by illustration at the risk of death.

SOMETHING NEW FOR THE SICK ROOM.—Under the name of pulmonary candles, Field & Co., English chandlers, have introduced candles containing in their substance some of those gum resins, and balsams, especially benzoin and storax, which from time immemorial have proved useful in chronic bronchitis and allied maladies. When burnt, the candles yield by the combustion of these drugs, a pleasing fragrance, and at the same time, give a good light. Candles are not much used in this country, but the idea might be adapted by the medication of kerosene. The aromatic odor alone would be an improvement of the fragrant combustible.

DIABETIC BREAD.—M. Danneby proposes the use of bread made from roasted flour for diabetic patients, instead of gluten biscuit. He asserts that roasted starch cannot be converted into glucose, and that bread made out of the various farinaceous torrefied is greedily eaten by patients who have been restricted to the ordinary preparation of gluten until they have become thoroughly disgusted. Moreover, under its use the thirst lessens, and the digestive derangements are remarkably ameliorated.

USEFUL INFORMATION.

WHAT BECOMES OF OLD LEATHER.—In addition to the answers given to this question in previous issues, we now add an improved process of utilization, invented in France and Denmark. At the late exhibition in Vienna, leather was shown suitable for heels, toe-caps, and inner soles prepared from leather clippings, by simply mixing them with some adhesive substance, forming the mass into rectangular plates on top of each other, subjecting them to hydraulic pressure, and then drying and rolling them. This article was restricted in use because it could not withstand moisture. A Copenhagen firm, however, exhibited for the first time an article made upon an entirely different plan. The leather scraps were first converted, in a suitable machine, into a sort of leather wool, which was mixed with caoutchouc and different chemical reagents, kneaded by machinery into a thick pasty mass, and then formed in metal molds, and dried and subjected to a gradually increasing pressure until it was finished under 6,000 to 10,000 pounds to the square inch. The appearance of leather is imparted to it by a light coating. Articles manufactured from this material are said to be 50 per cent. cheaper than those made from leather, and can be made in the same manner, while at the same time they are perfectly water-proof. It consists of about 41 per cent. of caoutchouc and 60 per cent. of leather.

FOR CEMENTING IRON-RAILING TOPS, ETC.—A correspondent of the *English Mechanic* states that he has found the following composition completely successful for cementing iron-railing tops, iron gratings to stoves and other similar applications, and with such effect as to resist the blows of the sledge-hammer, namely: Equal parts of sulphur and white lead with about a sixth of borax, these being thoroughly incorporated together so as to form one homogeneous mass. In applying this substance to either of the purposes named it is moistened with strong sulphuric acid, and a thin layer of it placed between the two pieces of iron, and these are then firmly pressed together to form a perfect union. In about five days it becomes perfectly dry, all traces of the cementing compound having vanished, and the iron exhibits the appearance simply of having been welded together.

An absolutely indelible ink—one that cannot be removed for the purpose of substitution—is a desideratum greatly needed. Galignani states that the French Stamp office has just purchased a secret of the composition of such an ink, and which resists the strength of all known reagents. Owing to that discovery, it is thought that it will be able to put an end to the numerous frauds which are constantly committed to the prejudice of the Treasury, and which consist in restoring to stamped paper already used, its original purity. The annual loss to the revenue on that head is calculated at 600,000f. in the Department of the Seine alone.

SOFTENING FILES.—Cover them with oil and hold them over the fire till the oil blazes; as soon as the flame runs all over the file, plunge it in water; or put them in a moderate hot oven for half an hour, if large files; but, if small, the first plan is the best.

THE DELUSION OF SMELL.—The sense of smell, like the others, has its aberrations and hallucinations. The delusions of smell are hardly ever isolated; they accompany those of hearing, sight, taste and touch, and are also less frequent than the latter. Insane people who are affected by their complaint of being haunted by fetid emanations, or congratulate themselves on inhaling the most delicious perfumes. Lelant mentions the case of a woman, an inmate of La Salpêtrière, who fancied that she constantly perceived a frightful stench proceeding from the decay of bodies she imagined buried in the courts of the institution. Impressions of the kind are usually very annoying. Pierre de Beismont relates the account of a woman, affected by disorder of her senses. Whenever she saw a well dressed lady passing she smelt the odor of musk, which was intolerable to her. If it were a man, she was distressingly affected by the smell of tobacco, though she was quite aware that these scents existed only in her imagination. Copelin mentions that a woman who declared that she could not hear the smell of a rose, was quite ill when one of her friends came in wearing one, though the unlucky flower was only artificial. Such facts might be multiplied, but as they are all alike, it is not worth while to mention them. The latest observations made in insane asylums—among others those of M. Prevost, at La Salpêtrière—have shown also that delusions and perversions of the sense of smell are more common than had hitherto been supposed among such invalids, and that if they usually pass unnoticed, it arises from the fact that nothing spontaneous denotes their existence. —*Popular Science Monthly.*

EARLY USE OF COAL.—A contemporary says: Coal is not, as is generally imagined, a modern form of fuel. The Chinese, forefathers in most discoveries, knew its value centuries ago. It is known to have been in use in the days of Julius Cæsar and the Roman Empire, and from the twelfth century to the present day the trade in coal has undergone progressive development. As long ago as Edward the Sixth's reign, toward the middle of the sixteenth century, coal was shipped from England to France, a letter of that date speaks of "that thing that France can live no more without, than the fische without water; that is to say, Newcastle coals; which without that they can neither make steel work nor metal work, nor wyre work, nor goldsmiths work, nor gonges, nor no manner of things that passeth the fier."

TO PREVENT RUBBED SHOES FROM LOOKING DINGY.—This is a difficult thing to accomplish in any other way than by a daily application of means for removing the dirt. The action of sun, heat, dirt and water, attacking the coating of rubber, and impair its coloring matter. Heat softens the rubber to a certain extent, and allows the dust to fix itself not only on but in the rubber. The dust particles, to whatever extent they are present, contribute a dingy appearance, which cannot be permanently removed. We know of no better plan than to wash the foot frequently with warm water and castile soap; after which rub the top with a flannel rag moistened with sweet oil, going over the top a second time with a dry rag in order to remove the oil. The remedy is only a temporary one, and therefore must be repeated whenever the rubber is soiled.

PURIFYING LINSEED OIL.—It is requisite that artists should have the linseed oil they use perfectly colorless, or otherwise they would spoil the more delicate tints. To purify it is extremely easy. Even putting a bottle in the sun for some days will accomplish the object; but as this process is somewhat tedious, it is better to put in a 2 oz. vial, three-quarters full of good common linseed oil, a piece of whiting as big as a nut, previously powdered, and shake them together and put the vial in an oven. In two days, and sometimes in a few hours, the whiting will have carried down to the bottom all color and impurity, and the refined oil floating at the top may be poured off for use.

REGULATING A COAL STOVE.—Never fill a stove more than half or two-thirds full of coal, even in the coldest weather. When the fire is low, never shake the grate or disturb the ashes, but add from ten to fifteen bunches of coal and turn the draft on. When these are heated through and somewhat ignited, add the amount necessary for a new fire, but do not disturb the ashes yet. Let the draft be open a half an hour. Then shake out the ashes. The coal has thoroughly ignited and will keep the stove at a high heat from six to twelve hours, according to the coldness of the weather. In very cold weather after the fire is made, add coal every hour. —*Coal Gazette.*

GLUE.—Glue loses much of its strength by being often melted; that glue, therefore, which is newly made is much preferable to that which has been used. When done with, add some of the boiling water from the outer vessel to the glue, so as to make it too thin for use. Put it away till wanted again, and by the time the water in the outer vessel is boiled, the glue in the inner is ready melted, and the proper thickness for use. Powdered chalk, brickdust, or sawdust added to glue, will make it hold with more than ordinary firmness.

The odor of a phial that has contained medicine may be removed by filling it with cold water and letting it stand in an airy place, uncorked, for three days, changing the water every day.

DOMESTIC ECONOMY.

The Products of Gelatine.

The interesting and singular fact appears that millions of dollars cover the value of the gelatine industry in this country, and this value is said to be still greater in Europe. The purest form of commercial gelatine is known as isinglass, the best being prepared from the air-bladders and sounds of three or four species of sturgeon. These tissues are cleansed, dried and scraped, forming what is termed leaf isinglass, or they are twisted into various forms called long and short stople, or folded into packages called book isinglass.

The Russian isinglass has always held the highest rank in the market, but its manufacture is very simple. The swimming bladders of the fish are first placed in hot water, carefully deprived of adhering blood, cut open longitudinally and exposed to the air, with the inner delicate, silvery membrane upward; when dried, this fine membrane is removed by beating and rubbing, and the swimming bladder is then made into the forms desired.

Machinery is employed to cut isinglass into the delicate filaments in which it is usually sold. A solid gelatine, in thin plates and strings, is manufactured in large quantities in France, to answer the purpose of isinglass. The best is transparent, and is prepared from the gelatine of bones, by digestion in dilute hydrochloric acid and long boiling in water. It is much cheaper than the first described article, as well as decidedly inferior. The same may be said of another variety, known as opaque gelatine, which is prepared from the cottings of skins.

A GOOD BED.—A most soft, comfortable, and wholesome filling for beds or for mattresses, can be procured in most country places by getting a farmer, when threshing to allow oat chaff to be saved. It is soft, light and elastic, and when new and clean is very sweet. The cost is very light, only the cost paid by the farmer for the men saving and sifting it. As oat chaff is rarely used for cattle food it is easily obtainable. It is so very light that a slighter kind of bed-tick than is necessary for other kinds of filling is quite sufficient for oat chaff. Another advantage is that it can be changed every year at so little cost that it is within the reach of many if not all. For children's beds it is perfectly satisfactory. It is only necessary to keep a sack or two stuffed full of oat chaff in a dry place, and then new and fresh filling is at hand to make a sweet bed whatever accident may have befallen the cot mattress. Next to the chaff is clean oat straw for bedding. Indeed, we would make this our first choice, after the more cleanly met for all adults. It should be changed frequently and always be kept sweet and clean.

GLYCERINE FOR PRESERVING FRUIT.—We learn through a German journal, says the *Journal of Applied Chemistry*, that in order to preserve fresh fruits it is only necessary to heat them, if not perfectly ripe, in water almost to boiling, drain nearly dry and cover with warm, concentrated glycerine. If the fruit is perfectly ripe heating the water is unnecessary. It is also advised to pour off the glycerine after standing for some time, and add fresh concentrated glycerine on a water bath and use a second time. Ordinary glycerine is often impure, but only that which is perfectly pure and colorless, with a clean, sweet taste and a specific gravity of 1.25 should be employed.

VIENNESE MEERSCHAUM.—The product known as Viennese Meerscham is prepared by mixing 100 parts silicate of soda with 60 parts of carbonate of magnesia and 90 parts of the native meerscham or pure alumina. This mixture is then pulverized with the greatest care, and passed through a sieve of very fine silk or horsehair; add water, and boil it for ten minutes; then pour the whole into moulds, placed so that the water may separate easily.

GLUE TO RESIST FIRE.—The *London Furniture Gazette* gives this recipe: Mix a handful of quick lime in 4 oz. of linseed oil; boil to a good thickness, then spread on plates in the shade and it will become exceedingly hard, but may be easily dissolved over the fire, and used as ordinary glue. It resists fire after being used for gluing substances together.

CRAYONS FOR DRAWING ON GLASS.—Melt together equal quantities of asphaltum and yellow wax; add lampblack, and pour the mixture into moulds for crayons. The glass should be well wiped with leather, and in drawing be careful not to soil the glass with the fingers. In trimming these crayons, the point may easily be rendered very fine.

OYSTER OMELET.—Whisk four eggs to a thick froth, then add by degrees, one gill of cream; beat them well together; season the egg with pepper and salt to taste. Have ready one dozen fine oysters; cut them in half and pour the egg into a pan of hot butter and drop the oysters over it as early as possible. Fry a light brown and serve hot.

RESTORING IVORY.—Discolored ivory may be restored to its original whiteness by cleaning it with a paste, composed simply of burnt pumice stone and water. After cleansing, place the article under the glass in the sun's rays.

TABLE OF CONTENTS.

EDITORIALS AND GENERAL NEWS.—
 Reduction of Silver; Road and Fire Locomotive;
 Mining Decisions; Hydraulic Mining, '72. The Evening Post Parrot, '73. Gold: A Close Call; Danger at Nevada; A Valuable Brick; Pensioners; A Black Day; Alviso Railroad, '73.

ILLUSTRATIONS.—Traction Engine, or Road and Feed Locomotive, '65. Economic Botany; Hydraulic Mining in California, '73.

CORRESPONDENCE.—Cherry Creek Mines, '68.

SCIENTIFIC PROGRESS.—The Unity of the Universe; Disintegration of Glass; Another Explosive—Ozobenzene; Respiration and Nutrition in Plants; New Application for the Spectroscope; Protection Against Hail as well as Lightning; Effect of Flame on an Electric Spark; Is Hydrogen a Metal? Technical Schools; Astronomical Science, '67.

MECHANICAL PROGRESS.—Economic Method of Drying Foundry Molds; Metallic Floors; New and Wide Use for Infusorial Earth; Coating Iron with Copper; The Future of the Iron Trade; Producing a Brown Color on Iron; Giving Iron Wire a Silver White Appearance; Molecular Change in Iron; Coating Iron with Brass, '67.

MINING STOCK MARKET.—Thursday's Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of Stock Market for the Week, '68.

MINING SUMMARY from various counties in California and Nevada, '69.

USEFUL INFORMATION.—What Becomes of Old Leather; For Cementing Iron-Railing Tops, Etc.; Softening Pipes; The Delusion of Small; Early Use of Coal; To Prevent Rubber Shoes from Looking Dingy; Purifying Linseed Oil; Regulating a Coal Stove; Glue, '71.

GOOD HEALTH.—Consumption of the Lungs; Impurities in the Atmosphere; The Heat of the Body; Risks his Life on his Faith; Something New for the Sick Room; Electric Bed, '71.

DOMESTIC ECONOMY.—The Products of Gelatine; A Good Bed; Glycerine for Preserving Fruit; Viennese Meerschaum; Glue to Resist Fire; Crayons for Drawing on Glass; Oyster Omelet; Restoring Ivory, '71.

MISCELLANEOUS.—Fast Riding to Secure a Re-Location; Bonanza in the Iron Mines; The Richmond Mine; Excceedingly Rich; Miners' Chances; Colorado Gravel Mines; The Gold Hill Chasin; Mill at Tybo; Engines for the River Mills; Rough on the Agents; Naval Machinists; Our Iron Mines and Lincoln Coal; Black Jack; Nevada Coal Mines, '70. San Francisco Iron Works and the Bonanzas; Quartz Jumping; Los Angeles Chamber of Mines; The Mining Companies; Another Big Gravel Operation; The Shallowest Draught Steamer in the World; Chrome Iron Mines in California, '74.

Concentrating.

It is stated that a company of California capitalists intend putting up works in the vicinity of Helena, Montana, the coming season, and will purchase and ship quartz. Perhaps if some concentrating works were put up in different localities on this coast our bullion yield would be larger. Many camps which ship ore for reduction, paying enormous sums per ton, can scarcely be kept running on account of high freight charges. It costs no more to ship rock worth \$1,000 per ton than it does rock worth \$100 per ton. If ten tons could be concentrated into one, at half the cost of the freight on a ton, it would pay then 50 per cent. more than now.

We ship each year thousands of tons of ore out of the country paying so much per ton freight, a large percentage of which could be saved to us, besides giving employment to home workmen. In other countries much more attention is given to concentration than here, and with good results. We still go on shipping hundreds of tons of worthless gangue, and paying heavy freight on it, which could be avoided by concentrating the ores before shipping. The farmers ship the grain and throw away the stalks; the miner ships the metal and the dirt with it, paying an equal freight on both. The circumstances are not exactly parallel, but are similar enough for illustration.

We trust it will not be long before steps are taken in the right direction in this matter of concentration. Arizona, for instance, would make a much better showing to-day if she had commenced concentrating a few years ago. She ships rich ores to this city which pay all the heavy freights and a fair profit. With ten tons in one, or even five in one, the profits would be much greater, as the freight per ton would be twice as heavy as the concentrating expenses per ton. Not only Arizona, however, but many places in our own and neighboring States would do well to pay some little attention to this subject. We feel confident that in a few years the subject will become even more important than now.

CALISTOGA shipped 138 flasks of quicksilver last week.

The New Almaden Mine.

We give in the accompanying table a synopsis of the result of operations at the New Almaden mine, Santa Clara county, California, for twenty-two years and three months, kindly furnished by J. B. Randol, Superintendent. This is one of the principal quicksilver mines of the world, as its record shows, and is the most productive mine in the United States. Within the past few years the product has fallen off somewhat, but it still retains its position at the head of the quicksilver mines of America. It will be noticed that the product of the mine during 1874, was lower than during any previous year while being worked continuously, and also that the percentage in the ore was smaller. The falling off in production of this mine is one of the chief reasons of the present scarcity of quicksilver, and all of the other mines discovered in California have yet been unable to make up for the deficiency of the New Almaden. The demand for the article has also increased very materially, and for the past two years the mining interests have been burdened by the very high price of quicksilver.

In our annual mining record last week we stated that the supposed product of the Redington mine, in Napa county was 1,000 flasks per month during 1874 which, if true, would have made the product larger than that of the New Almaden. This was merely supposition, however, based on rumor, and we have since learned that the product of the Redington was correct as given in the *Commercial Herald*—7200 flasks. This makes the product of the New Almaden still remain, as it always has been heretofore, greater than any mine in America.

In some part of our review we stated that there were six Almaden furnaces, meaning, of course, "New Almaden" furnaces. Those, however, inexperienced with metallurgy of quicksilver, might suppose that these furnaces are similar to those so well known and for so long a time in use at Almaden in Spain. But they are essentially different in their charging, firing and condensation. The furnaces we referred to were "New Almaden furnace," such as are also in use at many other mines on this coast. The new furnace being built and which will soon be in operation at New Almaden, is not of the old style but is a continuous furnace modeled after the latest iron-clad furnace in most successful operation at Idria, Austria, with many improvements, some of which have been kindly furnished to the New Almaden company by the engineer of that mine.

A glance at the table given above shows a carefully kept record of the operations of the mine. If other Superintendents of leading mines were to follow the example of Mr. Randol in this respect we might have more valuable data with respect to the operations of the gold and silver mines of the coast.

DEATH OF PROFESSOR DURANT.—Henry Durant, Mayor of the city of Oakland, and ex-President of the University of California, died suddenly on Saturday last. The funeral services were performed on Monday at the First Congregational Church, and were largely attended. Many of the stores were closed, and the occasion was one of the largest gatherings in honor of the dead that has ever taken place in Oakland. The cortege moved to the burial ground in the following order: The Faculty of the University of California, Alumni of the College of California and of the University, the Berkeley Club, pall-bearers with coffin, City Council, Board of Education, Board of Health, police force, officers of the Fire Department and other city officials, University Battalion, Cadets of Military Academy of California, (McClure's), students of the Golden Gate Academy, and citizens. Professor Durant was an honored and highly respected man, and his loss is deeply felt.

AUSTIN, Nev., shipped 994 bars of bullion during 1874, weighing 91,914 pounds, and valued at \$1,165,594. The bullion was almost entirely the production of the Manhattan 20-stamp mill.

Mining Decisions.

The Secretary of the Interior has decided, in the case of the City Rock and Utah claimants vs. W. H. Pitts, et als., applicants for patents for the King of the West lode, Utah, that: "A mining claim, so far as the surface ground is concerned, must conform to the location notice and record. The law of May 10, 1872, expressly declares the rights of parties owning lodes which meet or unite. The question of how far the General Land Office may extend its examination into the sufficiency of an adverse claim considered. An adverse claimant must positively allege ownership. An adverse claim which is bad on general demurrer should be rejected."

"The appeal from the decision of the Commissioner of the General Land Office, regarding the survey of the California land claim, Los Prietos y Najalayegua, has been withdrawn by the attorneys for appellants, in consequence of a private agreement or compromise between the grant claimants, represented by W. W. Stow, and the mining interests, championed by Harvey Brown."

In our issue of January 9th we expressed the opinion, in answer to a correspondent, that a miner could only locate 1500 feet, on one ledge. Our correspondent stated that he had located 1500 feet and then moved 10 feet away from the end of his claim, sunk a shaft and claimed 1500 feet more. The mining law of May 10, 1872, says that a mining claim located after the passage of the Act whether located by one or more persons may equal, but not exceed, 1500 feet along the vein or lode; but no location of a mining claim shall be made until the discovery of the vein or lode within the limits of the claim located. It was understood that this special provision was intended to prevent one party from locating four or five miles of croppings to the exclusion of others; and that, in connection with the Government requiring annual expenditure, indicates that Congress intended to confine claims to smaller boundaries.

The *Silver State*, a Nevada journal which pays a great deal of intelligent attention to the mining interests, called our attention to this matter, stating that we were probably mistaken in our opinion that a miner could not locate more than 1500 feet on one ledge. In looking over the rulings of the Commissioner of the General Land Office we find the following ruling by W. W. Curtis, Acting Commissioner of the Land Office, in answer to an inquiry: "Referring to your letter of the 13th ult., I have to state that the Mining Act of May 10, 1872, declares that a mining claim located after the passage of this Act, whether located by one or more persons, may equal, but shall not exceed one thousand five hundred feet in length along the vein or lode."

"But there is no provision of law to prevent parties from locating other claims upon the same lode, outside of the first location made on the lode or vein."

"If a lode or vein three thousand feet in length is discovered, two locations may be made each of 1500 feet thereon."

Although the rulings of the Commissioner are not law, they are authority until legally reversed; so that the opinion previously expressed by us was incorrect.

Lodes carrying rich ore in small quantities and scattered veins, in Colorado, are now made to pay well by means of concentration works; and veins carrying only thirty ounces of silver per ton and running forty per cent. lead, find a ready market at prices that afford a good margin of profit where the veins are strong.

Times are said to be rather dull in White Pine at present but the future is promising. The English company keeps its mill steadily at work, some 50 tons of \$60 ore being taken from the mines daily.

Hydraulic Mining in California.
No. 10.

In Fig. 12, twelve electric fuses are inserted in the different drifts. These fuses are marked in the circuit of the leading wire, A A, and are buried equidistantly in the powder. The main drift, from the point where the first cross-drifts intersect, that is, for a distance of 65 feet from the mouth, is safely closed by first making a barrier of timbers across the main drifts, where the intersection takes place, and then filling the main drift with sand and fine gravel tightly to its very mouth. The blast is now ready for explosion.

The blasting apparatus, B, being established at a safe distance, and the two leading wires attached to it, the crank of the frictional apparatus is turned in this instance 22 times to the right, and then reversed for about six inches, when the discharges of all the fuses take place at the same moment. It is laid down as a rule that ten turns are taken for the first fuse and one for every additional one.

When greater areas of ground than that mentioned above are to be blown up the main drift must be extended, and additional and longer cross-drifts must be made. The powder must always be distributed with regard to the work it will have to perform; a little experience and better acquaintance with the deposit to be blasted will soon lead to the proper treatment of the ground.

However, as a general rule, it may be said that a strong charge of powder should be employed. The extra expense for powder is easily repaid by the thorough breaking up of the ground, securing not only a greater yield of gold, but lessening also the manual labor to such an extent that the cost of an additional 100 kegs of powder, or any proportion thereof, becomes insignificant.

Shafts with a J in the bottom are excellent for high banks, and have all the effect of drift-blasts. Besides this, it is much easier to fill or tamp them than a level drift, as the material extracted from them is deposited round their mouths, and can readily be thrown back as tamping.

To secure from injury the insulated wire, which is to be connected with the blasting apparatus, it is advisable to cut a little groove for each wire, leading from each arm of the cross-drift to the mouth of the shaft or main drift.

In case water should be found in the drifts or shafts it is necessary to use for the powder boxes made water tight with the help of tar. The lids are perforated with gimlet holes for the admission of the fuse. After the fuse is inserted the lids are placed firmly on the boxes, either with screws or wooden wedges, and the gimlet holes are closed either with wax, soap, putty, or even clay, leaving everything well protected.

To blow up patches of bottom gravel 10 to 20 feet deep, bottled shaped shafts are used. These are sunk from four to five feet in diameter to the necessary depth, say 18 feet, and their bottom is widened all round from two to three feet beyond the original periphery of the shaft.

The powder is placed in the lower excavation all round. In the center a layer of heavy rocks is placed, to be the basis for the filling or tamping material, and to prevent the latter from entering the excavated part. The shaft is tamped and the explosion takes place with generally an excellent result. The ground will be crushed from 15 to 20 feet in every direction from the shaft and will yield readily to the hydraulic jet.

Giant powder blasts have been tried in several hydraulic mines with great success, according to the published reports. Giant powder No. 2 is used for this purpose.

In all blasting operations, from the simple hand-drill blast, removing only a few hundred pounds of rock, to the bank-blast, removing thousands of tons, a careful calculation of the strong and weak points in the material attacked should precede the placing of the blasts.

Condensed from an article by Charles Waldeyer, of the last Annual Report of the U. S. Commissioner of Mining Statistics.

Economic Botany.

Lecture Delivered before the University of California College of Agriculture on Monday, Jan. 14, by Prof. C. E. Bessey, M. S., of the Iowa College, Ames, Iowa.

[Reported expressly for the Press.]

I must first make a little correction of the definition of "economic botany," given in the circular describing this course of lectures. This definition should include plants which are harmful to man; so, in putting down your definition of it please include the two terms, useful and harmful. And when we speak of useful plants, of course we mean those which furnish food for man and the domestic animals, which furnish medicine for both; and covering for both, and after having taken into consideration these two things there are a good many extras, things which we may lamp; for instance a great many ornamental plants that must necessarily come in. On the other hand, harmful plants would include all of our weeds, all that are poisonous and the plants that we take up specially to-day.

The Parasitic Fungus Growths.

Now in this course of lectures we shall take up only a few, because, if we looked over the fifty or sixty thousand different species, it would be more than a dozen lectures could possibly compass. We will, therefore, run through the groups from the lower to the higher. I want to call your attention to the cryptogams, which are of economic value; seaweeds, lichens; fungus plants, the liverworts, mosses, ferns, and their allies. Indeed, we can lamp these off in a very short time. We have here some of the very lowest forms of seaweed made up of single cells. Here we find frog spittle (conferia). Here, also, we have some forms that are found along your coast. This is found on the rocks. This little herbet is the little microscopic plant which dodges about as can be seen under the microscope, with amazing velocity. These are more or less inclined to be green in color, though, of course, some found in salt water have other colors. Of substances practically asexual to man they furnish only iodine, which is pretty largely derived from them and Irish moss. Of lichens I have put down here the two more important products, Litmus, which is obtained from a little plant belonging to this group, and Reindeer moss, found in Lapland, covering the ground, as does grass. In the northern region it is used as food for reindeer. The Liverwort, or the *Hepatica*, you may put down as of no use whatever or their only use being to cover the ground and by their dying to furnish food for other plants. The same may be said of the mosses and ferns, if we except the utility of beauty. The one exception in mosses is the *asphagnum*—possibly found here—which is used for packing. To that excepting

The Fungals.

The Cryptogams are of no economic interest. First, as to what a Fungal is? The common idea is incorrect. The Fungal is always a plant growing more or less under ground, or under some surface, made up of white threads growing in every direction under this surface, whether it be the surface of live wood, earth, or what not, growing in every direction through this surface and finally fruiting in some form. The true plant then we must consider the part which grows under the surface or under the ground. The puff ball as we find it is one of the fruiting forms.

A little more as to what this growth is beneath the surface. All cryptogams grow from spools. The spool falls upon the ground and is then only a little round cell. It begins its growth by multiplying and so has the form of elongated threads. These form the true plant. After a time, and this time may be likened to the time required by any ordinary plant, it sends up fruiting portions which we ordinarily observe. This may be taken as the usual manner of the re-production of Fungals.

Classification.

Fungals are divided into six groups, or orders, with the following characteristics. Spores in sacs. In sacs which are usually aggregated. Order I. *Helvellaceae*. In sporangia. Order II. *Mucoraceae*. Spores naked. On ends of conspicuous threads. Order III. *Bolrylaceae*. On inconspicuous threads. Order IV. *Uredinaceae*. On threads, enclosed in a peridium. Order V. *Lycoperdaceae*. On an hymenium. Order VI. *Agaricaceae*.

Under the first order are quite a number of injurious plants and a few valuable ones. First we have pea mould, which in its manner of growth is about like this. (See figure 1.) Probably you have all noticed that a great many leaves, not only of the pea but of other plants, are covered with a white mouldiness. Take one of these leaves and place it under the microscope and you will find over the whole surface myriads of threads now and then passing into a stomate, and of course sucking the sap from the interior of the leaf. These little threads form the *mycelium*, the proper fungous growth. It covers the leaves, stops up the breathing pores, and in fact chokes the plant upon which it is living. After the plants become fully grown, then it produces these little spore cases. (See figure 1).

By the use of a microscope of perhaps one

hundred diameters, you will find the leaf dotted over with little black dots. I have noticed on some of the plants on these grounds quite a number of remains of allied species. They are of quite considerable importance. Allied forms affect the rose, peach, pear and a great many other plants.

In many parts of the country plum, peach and frequently cherry trees are troubled with black excrescences, which are called

Black Knot.

This is the *spharia Miroloso*. We test fungous growths by finding the fruiting. For a long time people were at a loss to know what was until finally some man found the spores borne in this way. Standing at right angles to the surface, we find elongated sacs in which are the spores. You need not think to succeed in finding them with an ordinary lens. It requires a very good section and a good microscope in order to find them.

The only remedy for black knot is to cut off the knots as they appear. It is the only remedy that is available. Your only safety is to cut down the tree, or to cut away the branches. The branches effected by the knot must be cut off a considerable distance below these excrescences, as the *mycelium* extends far below them. If a tree is found to be thoroughly infested, cut the whole tree down, and burn it up as soon as possible. All applications recommended are not much to be relied upon. I will notice a few hereafter. Now, as a sort of offset to this species of *Spharia*, in all

parts of the world we have some which infest larvae of the beetle and many other insects, very many of which are killed by the *mycelium* growing through them, the larvae, and destroying them. That offset is again offset by another which takes hold of the silkworm occasionally.

The rye plant is very frequently known to grow into and take on a peculiar growth; that is, the grain instead of development into the rye grain, develops into a dark-colored elongated mass known as ergot, (the scientific name of which is *Claviceps purpurea*.) Two species of this order are used for food, and where they are used furnish the best edible from the Fungal group. In England, truffles—an under

ground growth—furnish a food of exceeding excellence. As it is not found here, we pass it by. The morel, however, is found here and throughout all the world in general appearance, about like this little sketch I have here, and is covered over with little pits. These are gathered when they are full grown, and are used very largely in eating. Its scientific name is *Morchella esculenta*.

Mucoraceae derives its name from its principal genus, *Mucor*, the mould which is found very largely upon bread, fruits, paste and such things. *Mucor musco*, the bread mould, consists of under-surface growth, made up of filamentous threads running in every direction, and finally sending up a little blue mould (as we call it); [see Fig. 2.] The general appearance is well shown in the figure.

Under the next division the spores are naked, and we have first this little *Aspergillus*, [Fig. 3.] It is sometimes found in the summer time on

bread and pie. It first grows under the surface. At the top, instead of bearing spores, it bears strings of spores. In *Aspergillus*, one of our common plants, this thread terminates in a very large bell, and upon this are little threads, while in *Penicillium*, these strings or threads pass off without having any of these large bells. These two, as I said before, are very common.

Penicillium Crustaceum

Is what is known as the vinegar plant. You will know that vinegar is the result of fermentation, and has in it always a stringy, peculiar substance, called this "mother of vinegar." It consists of long, thready masses. You have simply these fungus threads, corresponding to the ordinary mycelium of fungus plants.

what is called the "mother of vinegar." We have these three proper fungus plants.

The Potato Rot Plant

Belongs also to this group, and I have shown in Fig. 4 its general character as seen under the microscope. One of these spores falling upon the leaf of the potato begins growing, grows just the same as this one. [See a, Fig. 4.] The production of this growth is mycelium. It passes down through the leaf-stalk to the stem; in fact, infests the whole plant. The result of this taking nourishment is, the cells of the potato plant are injured and rot sets in, and the whole plant in a very few days is destroyed. The potato may in the meantime be green, seeming healthy; the plants may have a strong and apparently vigorous growth, but in a very few hours they wilt down, blacken and decay, with a most fetid odor. We account for it in just this way: This mycelium has rotted all parts of the plant; by acting upon all parts of it, the plant is destroyed in this rapid way. Now, when you come to examine Taking any fermented substance, by the aid of a microscope you will find a multitude of little cells which resemble these. They take on an elongated form, and produce what we call the "mother" in vinegar; or, the mycelium.

now *Oidium Tuckerii*. It attacks leaves largely. Of course you are prepared to expect mycelium penetrating the plant also. Now, this form of fruiting will refer to group No. III.

We have these spores produced, and then again spores are blown to other plants. After a while it produces a second kind of fruit, similar to fig. 1. We consider the second kind as entitled to the preference. They are *Erysiphe*. The discovery was made within the last few years. This discovery carries it back to *Erysiphe*. In one of its forms it belongs to this genus *Oidium*, and we refer it then to *Erysiphe Tuckerii*. This will show the need of studying a plant's whole history.

In group No. IV, *Uredinaceae*, we have what are called cluster cups and I find myself embarrassed without specimens and will have to rely on the rude sketches upon the board. You will find occasionally this under surface of leaves covered over with little yellow appearances, which under an ordinary lens, will show themselves to be little cups. Take one of these little cups and cut it through, forming a vertical section, and its appearance will be similar to Fig. 5. This cup is found to be filled with myriads of little spores. We have here in the figure, the species *Berberidis*, the Barberry cluster cups. Now there is

A History Connected with this Rust.

In France, for a great many years, farmers complained that wherever barberry was grown it produced wheat rust. The railroad had run lines of barberry hedge along the sides of the track. The farmers complained, and did not want that barberry there. Wherever it was grown, wheat and other grains were found to be covered with rust. Botanists said it could not be barberry rust, because the two were so different. The farmers still complained, and finally the railroads concluded they would make an experiment and cut out a mile of the hedge; and after a while another mile; and so on, taking into consideration the direction of the prevailing winds. After examination, they came to the conclusion that the farmers were right and the botanists wrong. The cluster cup *Oidium* finally develops *Puccinia* just as the *Oidium* finally develops into *Erysiphe*. It is possible that De Bary may be wrong yet. There are some botanists who will not give in yet. Evidence seems to be very strong in his favor. Fig. 6 represents simply one form of its fruiting.

The fact is, there is another fruit also midway between these two—[Fig. 7]—first, *Oidium* is produced on the barberry; second, round spores (*Uredo*); finally, elongated spores (*Puccinia*). That brings us to the elongated spores which produce

Wheat Rust.

Take a bit of stricken wheat, or heads of rye that are covered with rust, and you will find the stem having elongated, brownish patches; put a little of this brownish dust under the microscope, and you will find that it is made up of spores, with bodies elongated, having the shape of Fig. 6.

This is the *Puccinia graminis*; one of the most injurious we have; not because of the breaking out into the fruiting state—that does not do very much damage—but it is because of the mycelium. Notice whenever wheat is "struck with rust," as we call it, the heads do not fill well. Those little patches can not do much damage; the damage is done by this mycelium; this filamentous growth, probably all coming from a single spore, germinating and pervading the whole plant. You can very often tell just how far it went and how far down, by the patches of rust from bottom to top. It is this internal growth that does the most injury. It is not this "breaking out," as we call it.

I have been asked: "If you have watched this rust how is it that after certain hot, damp days, wheat and other grains are more likely to be affected by it?" The common opinion is that this rust is directly due to this dampness in the air. I have known a very good agriculturist to refer it to a morbid condition of the sap; the sap exuding and turning brown. There is nothing in it. These damp, hot days develop rust in just the same way that such days develop grass or any vegetable. That accounts for the fact, that always after such days we may look for a greater amount of this *Puccinia* upon the plants than at any other time.

NOTE.—All of the accompanying illustrations, with the exception of the toadstool, are highly magnified.

The "Evening Post" Party.

On Saturday, of last week, a large party of invited guests assembled at the head-quarters of the *Evening Post* to witness the workings of their new press, stereotyping process and mechanical appliances recently introduced there. Everything worked satisfactorily, and there was but one opinion expressed by the throng of visitors, which was, that the proprietors of the *Post* might well be proud of the exhibit. There was much in this display that was entirely novel to many of the guests, and expressions of extreme surprise and satisfaction were quite common. The editorial and composing rooms were also visited, and found to be of the highest order; and in a side room a luncheon in perfect keeping with the other departments, was spread before the visitors, who repaired thither occasionally to partake of the good things there provided. The occasion was a pleasant one in every respect. The guests were in excellent humor, while all connected with the establishment were fully up to the occasion in attention and courtesy.

San Francisco Iron Works and the Bonanza.

While examining the complete and splendid machinery of the Consolidated Virginia new quartz mill, one cannot help coming to the conclusion that the iron works, foundries and machine shops of California depend largely for their prosperity, and in a measure for their very existence upon the Comstock lode. Were the lode to give out as it was feared might be the case in 1865-6, and no more mills or hoisting works be erected, upon what would the iron manufacturing establishments of San Francisco rely for support? They would be compelled to discharge their hands, shut down work, and in many instances abandon business. Disastrous as the failure of our mines would be to Virginia, it would be felt scarcely less severely at the metropolis of the Pacific coast. But with increasing developments and fresh discoveries of ore bodies of fabulous richness, spring up additional

Demands for Machinery

With which to work them. Beside the other immense quartz mill which has been ordered by the California company, and which will be a duplicate of that just started into operation by the Consolidated Virginia, and the machinery which must be employed at the new hoisting works on the new shaft on the line between the property of the two companies, the Bonanza will furnish material

To many other mills, which will be hereafter leased or erected. In addition to this, mining all along the lead, but especially at the north and south ends, has received a new stimulus, which will lead to further and deeper prospecting in the old mines and the sinking of shafts in the new. The machinery for all these will have to be drawn from the iron works in San Francisco and Sacramento. As the wealthiest owners of our mines reside in California the direct effect of our prosperity is felt there in the payments of dividends and the rise of stocks, but the indirect effects are scarcely inferior. The construction of machinery, the supplies of nearly all kinds required along the line of the Comstock come from San Francisco, and the recent unparalleled discoveries here will give a new stimulus there to all kinds of business with which we are even remotely connected.—*Enterprise*.

QUARTZ JUMPING.—Since New Year's day, prospecting for veins of gold, silver and other precious metals has been an active business. The County Recorder has been filing pre-emptions of newly-discovered lodes in the mineral resources of the Territory. Snow and cold weather did not deter the bold fortune-hunters, who did not sleep, but watched and prayed for the true fissure in the numerous mining districts of the county. A party proceeded to a certain lead to re-locate the same, with all its dips, spurs and angles, at one o'clock in the morning, and found that other persons had performed this labor at fifteen minutes after midnight. The early bird catches the quartz. Many patient prospectors think that they are richer than they were in 1874, and some residents, who have lost the property which has been pre-empted by honest and energetic miners, do not act as if they had lost anything. We predict that the bullion product of this county will be increased materially by the development and working of these ledges during the present and future years. At least \$100,000 will be added to the circulating medium of this section during 1875, by the wise policy of Congress in refusing to grant another extension of time to the owners of quartz lodes.—*Montanian*.

LOS ANGELES CINNABAR MINES.—Mr. Herrick showed us a lot of cinnabar ore, which he brought from claims recently discovered in the Sierra Madre range, opposite San Fernando. He says he traced the peculiar stratum for over seven miles, and the croppings denote the presence of a lead of cinnabar the entire length. To satisfy us that the yellow, rotten-looking rock was really charged with quicksilver, he reduced a piece of it to powder, and laying it on a copper sheet saturated it with muriatic acid. In a short time the powder was reduced to a fine pulp. Then washing it off with water, the face of the copper plate was covered with an infinite number of quicksilver globules, which, under a magnifier, were brought out very strong. A species of black earth procured at the same time was subjected to the same process, and gave quicksilver results. This earth is very plentiful, and can be shoveled up by the cart-load, at points near the base of the range. If the Sierra Madre is a cinnabar-bearing range, it will, with the transportation facilities so near it, become the objective point of a vast industrial population.—*Los Angeles Express*.

A few days ago a wood-chopper discovered ore in the vicinity of Carlin. He took pieces of the ore to Carlin, and by melting in a blacksmith's forge, they proved to contain silver. The discovery created the wildest excitement at the railroad shops, and nearly all hands hastened to the mines to secure claims, about sixty ledges of which have been located. The principal ledges are named the Keystone, Argenta and Snsie.

The settlers on Puget Sound have the coal fever, and prospectors are upon every hill in the valley. Several new discoveries have been reported recently at Olympia.

Property in the Mining Counties.

For a number of years past, says the *Stockton Independent*, property in the mining counties has been greatly depreciated in value by enormously high rates of taxation. The burden has been as heavy as the people could possibly bear, and in some instances absolutely crushing. Many persons who accumulated fortunes during the flush days of placer mining by trading in the towns and villages stuck firmly to the spot where fortune smiled upon them, until at length they found themselves bankrupt. Others found their way to San Francisco, where they invested advantageously and are now rich. As a rule, those who retained the cash they had accumulated, invested in mountain canals, roads, brick and other buildings, have been thus far disappointed in realizing their expectations. When miners were flourishing, money was accumulated very rapidly by the local traders. The money was sent off, however, instead of being retained for the work of future development. The minees built up San Francisco with a rapidity that has no parallel in the growth of cities. Had one-half or one-sixth of the capital which has found its way from the mountains to the metropolis of our own State and to other States and countries been retained, no foreign capital would have been required to place machinery on every gold-bearing quartz vein in the interior. To those early settlers in the mountain towns and mining districts who have held their grip, struggled along without faltering and retained their foothold in a region where the work of development is only in a measure begun, the country owes a debt of gratitude. During the long season of slow change in the system of mining, the residents of the mining districts have been under a cloud which is at length beginning to vanish, but how rapidly it will wholly disappear, time and events can alone determine.

Happily, the prospect is gradually brightening, thanks to the tenacity and industry and energy of the courageous band who have not deserted the field which yet contains millions of hidden gold. Additional value will be given to property and new life infused into business generally in the mountain districts by the settlers procuring titles to their farms, orchards, gardens and minees. This will give a feeling of security which has not hitherto existed, and will lead to renewed activity, more extended labor and venture, and soon change the condition of affairs from chronic dullness to a sense of life and vigor in both old and new industries. We believe that the mining counties of California have passed through their severest ordeal, and that a prolonged period of prosperity is opening up before them. Property is appreciating in value, satisfactory exhibits continue to be made in heavy mining enterprises, and there is evidence of more hopeful anticipations and earnestness in productive pursuits generally. The extraordinary determination and unflagging vigor shown by the residents of Mokelumne Hill in their unconquerable struggle against adversity, may be alone accepted as a type of the general spirit and temper which animate and actuate the people of the mining counties at the present time.

ANOTHER BIO GRAVEL OPERATION.—Mr. A. J. Gould informs us that during the week he has purchased from Mr. L. V. Tefft one-half of his gravel claims near the Middle Fork, known as the Rock Creek claims. The claims were formerly owned by Tefft & Herbert but for several years have been owned by Mr. Tefft, and have been lying idle. Mr. Gould informs us that by concentrating all the water available, by a system of ditches, they will have a good head of water for about five months in the year. The bank of gravel is a splendid one, and cannot be worked out in a life time. Mr. Gould got some fine prospects and is satisfied that with proper machinery for working, that the claim will prove immensely valuable. Work will commence in the spring, but it will take the coming summer to get the claims in running order. We hope that the new company will be as successful as they anticipate.—*Plumas National*.

The Rippon mine, in Alpine county, was re-located January 2d, in accordance with the mining law of May 10, 1872, and will hereafter be known as Occident No. 1 and No. 2. It has been re-located in the interest of San Francisco capitalists, who intend to commence work on it next spring. The Rippon belonged to a San Francisco company that had expended over \$30,000 on it.

The ditches which conduct water from the mountains to the towns and mines on their line, over on the San Juan ridge, says the *Nevada Transcript*, are being utilized in floating flume-blocks from the saw mill above to the mines below. These blocks are sawed above Columbia Hill, and floated down the ditch to the points above and near San Juan, thereby saving several miles of hauling with teams.

The following is a statement of the bullion shipment of Austin for the year 1874: Bare shipped, 931; weight of bars, 91,914 pounds; value, \$1,165,594.80. No bullion was shipped in January.

The ledge discovered within a few hundred yards of the town of Unionville, Nev., is creating considerable excitement in that camp.

Edward Clark has been appointed Superintendent of the Great Western quicksilver mine, in Lake county.

The Shallowest Draught Steamer in the World.

The increasing necessity for effecting communication between distant places in foreign countries by means of water transit has, where such means of transit exists, led to a demand for vessels of a light draught in order to navigate very shallow rivers. Builders have gone on reducing the draught from two feet to one and even less, but as civilization spreads the navigation of still shallower streams and the supplying of still lighter draught boats become necessities. It thus happens that Messrs. Yarrow & Hendley, of Poplar, have been engaged to design and construct some steamers of exceptionally light draught for the navigation of the upper waters of one of the rivers in Brazil. These boats are intended chiefly for the conveyance of passengers, and the first of them has just been launched, and made a satisfactory trial trip on Saturday last. In all probability she is the shallowest draught steamer ever built, her draught, with steam up and fully equipped, being only seven inches. This formed one of the conditions imposed upon her builders. The others were that she would not draw more than nine inches of water with 20 persons on board, and that she should be of such a size as to be capable of being carried whole on a ship's deck to the Brazils. The steamer has, therefore, been built with a flat bottom, and has a length of 45 feet, and a beam of eight feet, with a depth of two feet. She is propelled by a pair of paddles 54 inches in diameter, two feet nine inches breast, and each having eight floats. Her paddles are driven by a pair of inclined direct-acting engines, with cylinders five and a half inches in diameter and ten inch stroke. She is roomy and comfortable both fore and aft of her engines, there being accommodation for about 40 persons in all. Upon her trial trip on Saturday, with 18 persons on board, she drew eight and a half inches of water. Her engines ran at an average rate of 80 revolutions per minute, which gave her a speed of about eight miles per hour. On her first contractor's trial she made the same speed with the same number of revolutions, and with 130 pounds of steam, the stated consumption of fuel being 40 pounds of coal per hour. The run made with the little craft from the Temple to Greenwich and back on Saturday was thoroughly satisfactory and demonstrated both her speed and handiness. Now that it has been satisfactorily shown that such a light draught is perfectly practicable, it will probably follow that districts hitherto unexplored and lying up rivers previously deemed unnavigable will be opened up and new sources of commerce developed.—*London Times*, November 5, 1874.

CHROME IRON MINES IN CALIFORNIA.—With all the excitement of the past year concerning the development of our silver and quicksilver mines, but little attention has been paid to the development of our chrome iron mines. This metal, which is of as much intrinsic value as gold or silver, is to be found in abundance in our State, and nowhere more so than in our immediate neighborhood. We also have the advantage over any other part of the State in which it is found, on account of our nearness to San Francisco, and the cheap transportation afforded by railroad facilities. It only needs some few of the many capitalists of the Bay City to be assured of its great abundance here, in order to induce them to erect smelting works at that place, or what would be better still, near our own settlement and build up a business which cannot fail to return great wealth to those engaging in it. This metal is also found in great abundance in some of the northern counties of our State, but owing to the want of railroad facilities for freight it is not a source of revenue to the owners of the claims in which it is found. The owners of one mine of this character in Del Norte county reside in one of the Eastern cities (Baltimore we think) and cannot give their mine the attention it demands. The same deposit near our own town (and there are many more valuable) would yield immense wealth if worked, and they could be developed at much less cost. Rich leads of chrome iron have recently been discovered and located by Dr. Michel and Mr. Dickenson of St. Helena, which, when worked, and the immense quantity of ore fully brought out will astonish those who have not given this matter the attention its importance demands. The mine is situated about half way between Santa Rosa and St. Helena. Deposits of this metal are also found near our town, and the day is not far distant when oborne iron mining will be as extensively carried on as is now the labor of getting out silver and quicksilver. We would invite the attention of capitalists who wish to embark in some profitable investment, to this subject. Millions of dollars of wealth lie hidden in the hills adjacent to our town, which only await the money of the capitalist and the strong arm of the laborer to bring to the surface.—*Calistoga Free Press*.

Two car loads of new machinery arrived in Virginia City on Saturday morning, for the American Flat mining company. This machinery is of the most powerful description and of the approved pattern. There will be little delay in setting it up, as the foundations for its reception were being built while it was being constructed in the workshop at San Francisco.

JASON SPRINGER, of San Francisco, has made arrangements for the location of a blind, door, and sash factory in Chico.

Ayer's Cherry Pectoral,
For Diseases of the Throat and Lungs, such as Coughs, Colds, Whooping Cough, Bronchitis, Asthma and Consumption.

The few compositions, which have won the confidence of mankind and become household words, among not only one, but many nations, must have extraordinary virtues. Perhaps no one ever secured so wide a reputation, or maintained it so long, as Ayer's Cherry Pectoral. It has been known to the public about forty years, by a long continued series of marvellous cures, that have won for it a confidence in its virtues, never equalled by any other medicine. It still makes the most effective cures of Coughs, Colds, Consumption, that can be made by medical skill. Indeed the Cherry Pectoral has really robbed these dangerous diseases of their terrors, to a great extent, and given a feeling of immunity from their fatal effects, that is well founded, if the remedy has taken in season. Every family should have it in their closet for the remedy and prompt relief of its members. Sickness, suffering and even life is saved by this timely protection. The prudent should not neglect it, and the wise will not keep it by for the protection it affords by its timely use in sudden attacks.

BALL'S
SWEEPING DREDGE,
A NEW AND VALUABLE
CALIFORNIA INVENTION,
Has been very lately well proven by performing a job of dredging at the mouth of San Antonio Creek, at Oakland, Cal.

There is but this one machine that has ever had these improvements employed. It is an old machine, formerly built for another device, and is unfavorably constructed for Ball's improvements; yet this first temporary experimental machine has filled a scow of eighty-five cubic yards in sixteen minutes in unfavorable digging. For durability, digging hard material and fast work, it has a reputation (supported by leading engineers) as having no equal.

Testimonials and references will be given on application to the inventor, who is the sole owner of patents (excepting having made an assignment of the one machine now belonging to the Central Pacific Railroad Company). Having resolved not to sell any rights unless upon a basis of actual work performed by a machine built by myself for the purpose of fairly establishing the worth of the invention, I therefore offer to sell machines or rights on the following plan, which is warranting the capacity of the machine by actual work:

I will enter into an agreement with any responsible party to build and sell a machine, scows and tender, all complete, and right of all my improvements in dredging machines throughout the Pacific Coast for \$20,000, warranting the machine to dredge six cubic yards per minute (to fill a scow at that rate). \$20,000 will buy little more than pay the cost of building the machine, scows, etc., all complete; therefore I am proposing to ask nothing for my patents unless my machine dredges more than six cubic yards per minute. But it shall be further agreed that in case (at a fair trial to be made within a stated time) the machine shall fill a scow at the rate of more than six cubic yards per minute, then \$10,000 shall be added to the price above stated for each and every such additional cubic yard thus dredged per minute, and for additional fractions of a cubic yard thus dredged in the same ratio the \$10,000 is to be added to said price above stated.

I will sell any other Territorial or State rights (either United States or Foreign) upon the same plan and at a lower price proportionately than the rights for the Pacific Coast.

I will sell a single machine with scows and all complete, and right to use the same in a limited territory, for \$20,000 on the same plan as above stated, but will add only \$2,000 to each additional yard over the six cubic yards per minute. Each machine is not to employ more than two 10x20 inch engines.

Payments to be made in U. S. gold coin on delivery of machine, as may be indicated by agreement.

Address,
JOHN A. BALL,
9v28-tf
Oakland.

TO COPPER SMELTERS, BLUE-STONE & SULPHURIC ACID MANUFACTURERS.

For sale or to lease the LEVIATHAN COPPER MINE, in Alpine county, California.

The ore, which is in the form of silicate, black and red oxide, and gray sulphide, with metallic copper finely disseminated, averages from two to five feet thick, and 15 to 50 per cent. copper. A few parcels taken out during exploratory operations, realized \$30,000 for bluestone. In sight, 2,000 tons 20 per cent. ore; on dump, 300 tons 15 per cent. Supply inexhaustible. Title perfect. Minimum present capacity, 10 tons per day, which may be extended indefinitely. Cost of extraction, \$2. There is also a stratum of sandstone 20 feet in thickness, impregnated with 26 per cent. pure sulphur. To a coin purchaser highly advantageous terms will be offered. For further particulars apply to Leurs Chalmers, Silver Mountain, Alpine county, Cal.

San Francisco Cordage Company.

Gold.

The second of the course of popular lectures given by the Professors of the University of California, in connection with the Mechanics' Institute, was delivered by Dr. Becker, on Saturday night last. The subject of the first lecture, a synopsis of which is given on another page, was "Silver." The subject of this lecture, also delivered by Dr. Becker, is "Gold." We append a synopsis of his remarks as follows:

I took occasion in my lecture last week to explain that all matter is built up of a limited number of uncombined simple substances or elements, and that a chemical compound is the result of the union of two or more of these elements, in such a manner that the resulting substance, or compound, exhibits properties essentially different from those which characterize any of its constituents. The tendency which the different elements show to unite with one another in chemical combination is very different. Some of them, iron, for example, unite with many others with great readiness, and consequently we are acquainted with a great many compounds of iron. Thus this element combines in no less than three different proportions with oxygen alone. One of these compounds gives the green color to bottle-glass; we are familiar with the second as iron-rust, and the third as the chief ingredient of the black scales which fly off heated iron when it is being forged. Other elements again show very little tendency to enter into combination, and form but few compounds, while even these few are very unstable, i. e., are very readily decomposed into their constituent parts. Pre-eminent among the chemically indifferent elements with which ordinary life brings us in contact is gold. Scarcely any substances attack it, and the few compounds into which it enters are destroyed, the metal being liberated, by the simple action of heat. As a consequence of its feeble chemical affinities, gold is generally found in nature in a native or metallic state. A single compound rarely occurs, and this is the telluride; tellurium being a very rare element somewhat resembling sulphur. Silver always accompanies the gold, and frequently there are traces of other metals associated with it, especially platinum. Native gold is sometimes separated from the minerals with which it is mixed in the deposits by simple washing, or by crushing and washing. With these operations metallurgy has nothing to do, since they are purely mechanical.

The Treatment of Auriferous Ores.

As we saw was the case with silver, gold never occurs in sufficient quantities, relatively to the accompanying "dead" rock, to be efficiently separated by treatment of the kind to which ores of the base metals are submitted—liquefaction by heat and separation by gravity—and we are therefore forced to complement the necessary volume by the addition of some other metal. When gold occurs with lead ores, the treatment is precisely the same as that I described in speaking of silver, and the product of the cupellation process is simply auriferous silver instead of fine silver. Before I describe the methods of separating the two, however, I will explain the process in which quicksilver serves to supply the requisite amount of metal—the amalgamation process. In amalgamation, as in all metallurgical processes, we must get our metals into a metallic form before accumulating them in a fluid state, in fact, reduce them. Gold, indeed, is usually already metallic in the ore, but it is frequently coated with firmly adhering substances, and thus does not present a metallic surface, so that, regarded from a strictly external point of view, a grain of the coated metal may be said not to be metallic. Silver, on the other hand, is comparatively rarely metallic, being most commonly united with sulphur, often with antimony, and sometimes with chlorine. These compounds, therefore, require to be decomposed before metallic silver can be presented to the quicksilver. As you have probably inferred from the company in which it is found, silver, too, is to be classed among the metals whose chemical affinities are weak, though much stronger than those of gold; and, in fact, silver will readily part with either sulphur or chlorine, if any substance possessing a greater affinity for them, be intimately enough mixed with the argentiferous compounds. Lead, mercury, copper, iron, and others, could be made to effect this decomposition, becoming chlorides or sulphides in the operation, and isolating metallic silver; but in order that a sufficiently intimate mixture may take place, it is indispensable that either the silver compound or the metal should be in a fluid state. Now the sulphide of silver is insoluble, and therefore only quicksilver is in a position to decompose it at ordinary temperatures. Above its melting point, lead, as we have seen, decomposes it very effectually. The chloride of silver, on the other hand, is soluble in a solution of common salt, or, more exactly, the chloride of silver and common salt form a compound soluble in water; and that compound can, therefore, readily be mixed with and decomposed by, for instance, mercury, copper, or iron. The compounds of silver and antimony, however, are not decomposed by the metals at ordinary temperatures, but we are able to turn them into chlorides. We thus have a choice of several ways in treating silver ore for the separation of metallic silver, preparatory to amalgamation. The chloride may be decom-

posed by iron, copper, or mercury; the sulphide by mercury only, and the antimonides only by a process of chloridizing, followed by treatment as a chloride. Sufficient quantities of the antimonides very often occur in silver ores to render chloridizing imperative, and the operation is thus one of such importance that I must endeavor to explain it, although it depends on a somewhat complicated series of facts. Two methods are applicable:

Dry Chloridation and Wet Chloridation.

If ores containing sulphur and antimony in combination with silver are well mixed with salt and green vitriol (a compound of iron and sulphuric acid) and heated together, the first action which takes place is the decomposition of the green vitriol into oxide of iron and sulphuric anhydride, a compound of oxygen and sulphur. This body attacks the salt, which is a compound of chlorine and sodium. In attacking the salt, the sulphuric anhydride is decomposed, part of it taking oxygen from the remainder and instantly uniting with the sodium of the salt to a solid compound, the sulphate of sodium or glauber salts, while the remainder of the anhydride forms sulphurous acid, the ill-smelling gas which is produced by the ordinary combustion of sulphur. The sodium being extracted from the compound of chlorine and sodium we call salt, the chlorine is set free. This free chlorine now attacks the sulphur and antimonides of silver, and forms a separate compound with each of the three substances—sulphur, antimony and silver—so that we get our silver as chloride, which was the object of the whole process, while the compound of chlorine with sulphur and antimony, being volatile, pass out of the furnace up the chimney.

We have now got our silver into the form in which it is soluble in brine and in which it can therefore be brought into such intimate contact with other quicksilver, copper or iron, as to be separated by them in the metallic state ready to alloy or amalgamate itself with the needful bulk of fluid quicksilver, and thus separate from the lighter and worthless gangue or "dead rock."

The apparatus used to effect the chloridation in this dry way is generally a reverberatory furnace, i. e., a furnace heated by the flame from an outlying fireplace. The chief peculiarity of reverberatory furnaces used for chloridizing is the comparatively small size of the grate. The material is spread out over the hearth in thin layer and very gradually heated, for fear of melting any portion of the ore. If fusion were to take place, the melted matter would form a varnish on the particles of ore and effectually protect them from the action of the oxidizing and chloridizing gases. During the roasting the material is thoroughly raked over at short intervals, to insure the exposure of every particle of the ore to the prevailing influences of the furnace. A vast number of modifications of the simple roasting furnace exist, constructed mostly with a view to diminishing the amount of labor necessary.

Chloridizing in the wet way, although in outward appearance utterly dissimilar to the dry process, is governed by nearly the same laws. If we mix the ores with salt and the sulphate of copper (blue vitriol or bluestone) instead of sulphate of iron, and add water, the sulphuric acid of the bluestone unites with the sodium of the salt to glauber salt, just as in the dry process. The copper of the bluestone at the same time unites with the chlorine of salt. This interchange of elements occurs because sulphuric acid has a much stronger affinity for sodium than chlorine has, or than it has for copper, and the copper and chlorine being thus set free, necessarily combine. The copper chloride now attacks the silver ores, giving up its chlorine to them and taking the sulphur or antimony. This seems strange at first sight, since as we know, copper will rob chloride of silver of its chlorine. The reason why it can be made to chloridize the silver in this case, is that it gets sulphur or antimony in exchange, for which substance it has a much stronger affinity than for chlorine.

Amalgamation.

Two species of apparatus are in common use for amalgamating—the European barrel and the Washoe pan. The European apparatus is a large, wooden barrel, or pair of barrels, provided with suitable openings for charging and discharging the material, and hung on horizontal axes, by means of which they can be slowly rotated. The barrels are generally provided with a movable, wooden lining, which can be replaced when needful. The ore intended for treatment in this machine is always chloridized in the dry way, and finely pulverized. It is charged into the barrels with pieces of wrought iron or copper and a certain amount of water and salt is added. The barrels are then closed and allowed to rotate until the mass is thoroughly smooth, and of about the consistency of honey, so that when a stick is thrust into it and afterward turned end for end, the mud will run down slowly without any tendency to separate into more solid and more liquid portions.

What the chemical action is during this period, we already know. The dissolved silver chloride, coming into the most intimate contact with the copper or iron is decomposed; metallic silver is formed, and the chlorine unites with the baser metal. Which metal is chosen depends on the nature of the ore, for not only will either iron, copper or quicksilver decompose chloride of silver, but iron or copper will decompose chloride of quicksilver, and iron will decompose chloride of copper. If, therefore, as is not infrequently the case, the

silver ores contain copper, and this comes into the barrel as soluble chloride, iron will separate it out, in a metallic state with the silver which is very undesirable, as it, too, must then be accumulated by quicksilver, rendering a much greater consumption of that metal unavoidable. When the ores are auriferous, therefore, copper is best employed to separate metallic silver in the barrel, for of course copper cannot decompose its own chlorides. From the watery solution which remains after the amalgamation is completed, the copper employed and the copper in the ore can be recovered by simply throwing iron into it. The copper used to precipitate the silver is also frequently argentiferous, and when this is the case, of course the silver it contains is separated out in the barrel.

We now have, then, a pasty mixture in the barrel, in which the silver exists in fine metallic particles. To this paste quicksilver is added, and the barrel is again set in rotation in order that the fluid metal may be brought in contact with each particle of the solid silver and dissolve it. In this way, we get a large amount of liquid and very heavy metal, which can sink in the practically fluid mud if allowed to do so, and accumulate in a separate mass at the bottom, precisely as in the last lecture we found that the argentiferous lead separates in the furnace from the fluid slag.

You probably observed just now that I was particular in describing the exact consistency to which the mass of pulverized ore is brought in the barrel before adding mercury. This is a very important point, and its neglect would dangerously impair the efficacy of the process, by preventing a thorough mixture between the quicksilver and the material. Quicksilver is 13.6 times as heavy as water and five times as heavy as quartz, which is the most important of all the minerals occurring in the dead rock. It is therefore quite plain that if our mud, consisting in the main of quartz and water, were thin, the quicksilver would simply remain at the lowest portion of the barrel, the mud floating upon it, unless the rotation of the barrel were exceedingly rapid; while, if the mixture were too thick, the particles could not move with sufficient freedom to insure a contact of each of them with the quicksilver.

When the silver has thoroughly united with the mercury, the mass in the barrels is thinned down with water, and the apparatus again set in motion for a short time, to facilitate the union of distributed globules of amalgam with the mass of metal. The contents of the barrel is then tapped from the bottom, and the amalgam is allowed to run into vessels prepared for it. As soon as mind makes its appearance, which is, of course, not until almost all the heavy amalgam has run out, the stream is diverted into settling apparatus, where nearly all the amalgam not tapped out in a mass is recovered. We have thus got out of the ore about ninety per cent. of the silver it contained, though the exact proportion varies with the character of the ores, etc.

The gold was amalgamated at the same time with the silver; but, while the gold has generally been in a metallic state for ages, and has therefore had every opportunity to coat itself with non-metallic substances, such, for example, as sulphur or iron rust, the silver was separated out as a metal just before the amalgamation proper, and was therefore as clean as possible. Hence, we do not get anything like the same proportion of the gold as of the silver into the amalgam, commonly only about half, and hence this method of working is applicable principally to ores the smaller proportion of the value of which is in gold.

Dr. Becker here described the process, as accomplished in the Washoe pan. He continued:

Gold and Silver in a Native State.

Where the gold and silver are nearly or wholly in a native state, as is frequently the case in quartz lodes, amalgamation rests on very simple principles. In the first place, gold is much heavier than quicksilver; consequently, if heavy gold and light rock are passed over a pool of quicksilver, the gold will sink through the mercury to the bottom, while the rock will float on the top, and may be carried off by a stream of water. If, as is always the case, the native gold contains native silver, the action of this law will depend upon the proportion of the two metals, for silver is lighter than quicksilver. A mixture of seven parts silver to four of gold would have just about the specific gravity of mercury; but this would be an unusually large proportion of silver. The separation by gravity is also affected by the physical condition of the gold. Not unfrequently gold has been deposited with minerals which are decomposed by the action of air and water, thus leaving the gold, though nearly pure, porous. In this case it may float on the quicksilver, in consequence of the air it contains, as a dry sponge does upon water. The mercury also acts by strict amalgamation. It will absolutely dissolve only a very small amount of gold; but, spread on a surface of that metal, it will reduce it superficially to a pasty, sticky condition; and, properly taken advantage of, this fact is of great use.

When Gold Occurs in Gravel

It is washed down sluice boxes, in which, at short intervals, there are small transverse troughs, or their equivalent, called "riffles," filled with quicksilver. In the riffles the mercury seems to act principally as a liquid of medium specific gravity between the gold and the gangue—the gold sinks to the bottom of the riffle and the rock passes on. In crushing batteries, on the other hand, the cementing property of the fluid metal seems to be the more

important. When quartz is stamped in a crushing mill the particles of gold are separated from the rock mostly in a state of very fine division. Now, of course, the smaller any object is, the greater the amount of surface in comparison to its volume; and the greater the surface the greater the resistance offered to its passage through any medium. Hence, very fine gold, though very heavy, will sink very slowly in water; or, what amounts to the same thing, it will be very easily carried away by a stream of water. If, however, we introduce quicksilver into the mortar where the gold-bearing quartz is being stamped, at least a portion of this fine gold will acquire a sticky surface, and when sticky particles come together they will unite to a large lump. These aggregated morsels of gold will readily sink, and will be saved. Thus we can, to a certain extent, remedy the blunder of Nature in not depositing all the gold in nuggets.

Amalgam.

All the processes of amalgamation have given us amalgam. There are really two sorts of amalgam—one solid and one liquid. The liquid amalgam is silver and gold dissolved in mercury, and there is undoubtedly a chemical union, though a weak one, between the substances. The solid amalgam some excellent authorities hold to be no chemical compound, but only particles of gold or silver, stuck together with fluid amalgam. The two can be separated by straining through buckskin or close cloth, and in practice the fluid amalgam is disregarded; at least, no attempt is made to extract the metal from it, both because the amount is small, and because it is found that the fluid amalgam collects clear gold more effectually. This is probably because it wets the gold more easily, pure mercury having more attraction for itself than for most other substances.

The precious metals are extracted from the thick amalgam by the very simple process of retorting. Cakes of the amalgam are placed in a horizontal cast-iron cylinder, closed at both ends, but provided at one end with a long, small iron tube, which has an elbow in it, so that the end can be placed over a receiver, and is cooled by wet cloths or running water. The retort stands over a fire-place, and when it is heated the quicksilver volatilizes, passes through the tube, in which it condenses, and leaves the bullion behind. The quicksilver collects in the receiver, and, of course, is used over again.

The lecturer then described the various processes by which gold and silver are separated, and in particular the method adopted on a large scale by sulphuric acid, and the wet process, by which gold is extracted without silver from ores.

A FIGHTFUL CHORUS.—Nothing strikes so unpleasantly upon the ear of an affectionate parent as the wheezing, snuffling, snoring, and hoarse voices of a family of children laboring under bad colds. A chorus of this dismal kind is kept up in some households the winter through, simply because the father and mother are either ignorant of the means of cure or are guilty of gross neglect. *Hale's Honey of Horehound and Tar* will establish quiet in three days. No cough or cold can resist its soothing influence.

Fike's Tooth-Ache Drops—Cure in one minute.

TO LUMBERMEN—\$100 in Gold.—Messrs. Emerson, Ford & Co., of Beaver Falls, Pa., whose advertisement may be found in another column, won the above prize; also the first prize silver medal for the best circular saw, and the first prize silver medal for the best cross-cut saw, and the two first prize medals for the best saw sawage and cross-cut saw attachment.

A GOOD PAPER.—The MINING AND SCIENTIFIC PRESS has entered its 30th volume. It grows better as the years roll, and is, without exception, the best paper published for California miners and artisans. If such papers were more generally circulated to the exclusion of the sensation trash of the cities, the State would be the gainer in wealth, morals and general intelligence. —*Tuolumne Independent.*

Mining Machinery.

TEATS' PATENT FURNACE.

TEATS' PATENT FURNACE

For Roasting, Desulphurizing, Chloridizing and Oxidizing Ores, etc. For the reduction of Gold, Silver, Lead and other ores, saving a larger percentage, at less cost, than any other invention now in use. Chloridizing Silver ore more thoroughly, in less time, with less fuel, salt and labor; also roasting Lead ore preparatory to smelting, better and cheaper than any other invention. The Furnace is so constructed that one man, of ordinary ability, tends five or more furnaces; controls them with ease; adding heat or air; stopping or starting at will; charging and discharging with ease. Also, Patent "Conveying Cooler," for conveying and cooling roasted ores, heating the water for amalgamation and the boilers at the same time. Saving the large space in mill (covered with brick or iron), and the labor of two men per day, exposed to the poisonous chlorine gases. Also, Patent Air Blast "Dry Kiln," for drying ores direct from the mine or breaker, saving fuel and labor heretofore necessary in drying ores for dry pulverizing. For description refer to MINING AND SCIENTIFIC PRESS, No. 18, October 31, 1874. For particulars address

D. B. MILLER & CO.,

No. 12 West Eighth Street, Cincinnati, Ohio

Circulars, &c., will be furnished, if required.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

(PATENTED MAY 20TH, 1874.)

Price Reduced to 16 Cents Per Pound.

SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally:

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburgh Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not outwear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness of first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 60 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to

1v29-3m

CAST STEEL SHOE & DIE CO., Room 1, Academy Building, S. F.

Stamp Mill For Sale at Ophir Canon, Nye County, Nevada. Midway between Austin and Belmont, belonging to the Twin River Consolidated Mining Co. A complete mill, comprising twenty (20) 800lb stamps, (dry-crushing) with Rock Breaker, Pans, Settlers, and entire outfit of milling appliances; together with an excellent engine (18x42), two tubular boilers and all requisite shafting, gearing, belting, &c.; valuable lot of Sierra Nevada timber in Battery frames and building. The whole is offered cheap. For further information apply to JAS. D. HAGUE, 17v28-3m 240 Montgomery St., S. F.

STEAM ENGINES AND BOILERS

Of all sizes—from 2 to 60-Horse power. Also, Quartz Mills, Mining Pumps, Hoisting Machinery, Shafting, Iron Tanks, etc. For sale at the lowest prices by

JOHN TAYLOR & CO.

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits. They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:

The pan being filled, the motion of the miller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Settlers made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill-men are invited to examine these pans and settlers for themselves, at the office, 229 Fremont Street, San Francisco.

TREADWELL & CO.'S

(IMPROVED)

Upright Safety Engines and Boilers.

(MADE BY THE NEW YORK SAFETY STEAM-POWER COMPANY.)

We would call particular attention to the graceful design and simple mechanism of this Engine Boiler, the form in not pleasing to the eye, but is also, that which secures the greatest strength and rigidity with a given amount of material. The Boilers, which are of the Upright Tubular style, with internal fire box, are of the best material and workmanship, and are all tested to 150 pounds per inch. The Boilers are of great strength, and it is therefore unnecessary to purchase a greater power than is actually required, while in cases of emergency these Boilers can be depended on for more than their rated power. The Engine is not fastened to or upon the boiler, and is therefore not affected by expansion, nor are the bearings over-heated by conduction, or the heat from the boiler. The high speed which is necessary for economy of fuel, is easily accessible—a great advantage. In complete in itself as a Portable Engine and Boiler, or the Engine can be detached from the boiler and run independently, if required. Its main points are simplicity, safety and economy. For printing offices, laundries, tanneries, ranches, small repair or machine shops, or for hoisting, wherever a small portable engine is required, they are peculiarly adapted. Over 500 already in use!

Iron Steam Pipe furnished with Fittings, etc. Coupling Joints of all sizes. Particular attention paid to Distillery Work. Manufacturer of "Garratt's Patent Improved Journal Metal." Highest Market Price paid for OLD BELLS, COPPER AND BRASS.

Cazin's Combination Ore-Sizer and Concentrator—One Plunger System.

[Covered by Letters Patent of July 2d, 1872, and recent applications.]

Containing a sizing apparatus (revolving screen) delivering two or four sizes of ore to two or four rows of sieves, each row independent of the other, and each having 6 sieves, each row concentrating according to specific gravity the special size automatically fed into it, resulting in the simultaneous continual delivery of separated materials, working 2d and 3d class ores into 1st-class ores of perfect cleanliness. It thoroughly separates native gold or copper from quartz or any other lode matter—galena and silver sulphurets from pyrites, baryta and quartz; and pyrites from quartz. Added to a battery of stamps these machines constitute a full system of ore concentration, sufficient in most cases for the requirements of western mines, with a capacity of 15 or 20 tons per 24 hours.

For particulars apply to,

The Protracting Sextant—A New Instrument for Hydrographic Surveying.

At the last meeting of the California Academy of Sciences, T. J. Lowry, of the United States Coast Survey read a paper on the Protracting Sextant (a new instrument for hydrographic surveying), which he lately invented; and having received the favorable opinions of Prof. Geo. Davidson and other distinguished scientists, geometers and hydrographers, as enabling one observer to do that for which two sextants and one protractor and two observers are now required, it is now given to the scientific world.

We have represented here in the annexed figure "The Protracting Sextant," consisting of a circle *D*, graduated to degrees and minutes from the zero point around by the right and left each way to one hundred and eighty degrees, and three radiating protractor arms, *f*, *g* and *h*. The arm *g*, is fixed with its true edge at the zero point of graduation, and the other two *f* and *h*, are capable of being revolved around the hollow cylindrical axis of the circle. Between this fixed, and each of these moveable protractor arms, we have an index arm—and each of these indices *m* and *n*, also fixed in the center of the circle a common center of motion, and carries an index-mirror mounted perpendicular to its plane of motion but slightly eccentrically so that the hollow axis of the instrument can be readily gotten at. Along these index arms *m* and *n*, are cut rectangular slots (whose longitudinal axes are radii of the circle), in which slide the projecting ends of the pivots which rivet the equal rectangular bars, *o*, *s*, and *u*, together. And these indices and protractor arms are so connected by means of jointed parallelograms that the right hand index-arm always bisects the angle included between the fixed and right hand protractor arms, and the left hand index always bisects the angle contained by the fixed and left protractor arms.

Now by a well known optical principle we know that the angular distance moved over by a mirror while measuring an angle is only one-half of the actual angle measured, and since each of the moveable protractor arms of this instrument is by means of this jointed parallelogramic gearing, driven along its arc simultaneously with and twice as fast as its corresponding index-arm (and mirror), we hence see that the angles included between the fixed and moveable protractor arms are the actual angles which the indices (and their mirrors) have measured.

The index mirrors *y* and *z*, may be mounted to move either in the same or in parallel planes, as shown in the forms of the writer's two-angle sextante described in the proceedings of the Academy, February 16th, 1874, and in the MINING AND SCIENTIFIC PRESS of February 21st, 1874. A horizon glass, *x*, half-silvered to admit of direct and reflected vision is attached to the frame of the instrument nearly opposite the index-mirrors, with its plane perpendicular to the plane of the instrument. The arms *f* and *h*, are clamped and adjusted with the ordinary clamp and tangent screws, *l* and *k*.

The requisite adjustments of the "Protracting Sextant" are the same as those of the ordinary sextant. When observing with the new Protracting Sextant, the hydrographer holds it lightly in his right hand and moves it until its face is in the plane passing through his eye, *i*, and the three objects *A*, *B*, *C*, whose angular distances are required, and then sets and clamps his index arm so that the reflected and direct images of the objects (say left hand and middle) of one of the angles which he is to measure, are not coincident yet approaching on account of the progress of the boat, then with the second index glass he makes the direct and reflected images of the middle and right hand objects coincident, and keeps them coincident with tangent screw until the first two objects become coincident, then clamps,

and he has the two angles observed at the same instant—and also has them set off on the proper limbs of the instrument simultaneously with, and by the same effort that measured the angles. And hence after measuring two connected angles with this instrument we have only to lay it down on the "Field Sheet" (which should always be spread on a board before the observer in the boat), and shift it until the fiducial edges of the three protractor arms traverse the three points, (representing the signals observed upon), and the center of the instrument will then occupy the relative place of the observer; now dot the center and the position is plotted, without any of those tedious transfers of angles from the limbs of sextants to the limbs of the protractor which are unavoidably incident to the execution of practical hydrography with the forms of sextants and protractors now in general use.

However, with the hydrographer, it is necessary to read the angles off of the instrument

jects very close should not be observed on account of the parallax of the instrument.

The Protracting Sextant should have supplementary attachments, (such as were described by the writer before the Academy, February 16th, 1874), so that angles between one hundred and forty, and one hundred and eighty degrees may be measured with equal facility with those of smaller magnitude. But these larger angles cannot be plotted in the usual way, for they are too great to be set off at the same time on the limbs of the instrument because of the jamming of the moveable protractor arms—now under this contingency if we have no tracing paper and don't wish to sweep the circles of position, then we may use the following easy and accurate method of plotting by supplementary angles, viz:—Suppose *A*, *B* and *C*, the left, middle and right hand objects on which are measured two angles, too large to be set off on the limbs of the protractor at the same time—then set off the supplement

problem), as shown by the writer at page 18 of Vol. 2, of "The Analyst." And, in fact, with one piece of tracing paper and the Alidade, the topographer can plot his position, by the three point problem—and with two pieces of tracing paper and the Alidade, he can plot his position by either the two or four point problems shown by the writer at page 146, volume 1, of "The Analyst."

This instrument also furnishes the ready means of orienting the sounding boat. If out in a bay, lake or river, or along near the sea coast and your compass functions badly, and you have while nudgeing or plotting, or for some other reason lost your bearings, and hence wish to catch some fixed object ahead or astern on the general direction of the line you wish to run—then take from the sheet, with the Protracting Sextant, the angle between some visible signal and the general direction on which you desire to continue your line of soundings, and then lifting the instrument to your eye, shift it until you bring the image of this signal into the horizon glass, and whatever fixed object this image then covers will be a point on the desired course. By this means, the hydrographer, even if out on a large expanse of water and swept about by winds and currents, with his compass creased by local attraction or the heaving of the waves, may "orient himself" and thus ply the helm more intelligently. And, in fact, by this maneuver, and by observing (and plotting as you go) twice or thrice as many angles as must necessarily be recorded, the boat can be steered without the aid of the compass. These practical hints will be found to come most opportunely to the relief of the distressed Hydrographer when surveying close in shore along much of the Pacific coast, with its beaches of ferruginous sand, or along the iron bound shores of lake Champlain, where the magnetic needle often becomes worse than useless.

In nothing will the skill and dexterity of the Hydrographer be more advantageously displayed than in deciding at once upon the line his boat is to pursue, and with the glance of intuition grasping all the conceivable combinations of visible points that will determine his position. But in practical hydrography no less necessary than this skill and dexterity, is rapidity of execution in determining positions; and, to this end, with two observers the requisite promptness and evenness of action are often found deplorably deficient, and that too, at moments the most critical. A sunken rock or reef is to be determined, and on it a sounding gotten. The rock is found, the "cast" is taken—the word "stand by for an angle" is given—and at length comes the response, *r-a-d-y*; by which time perhaps a tangent screw is jammed (hard up,) or the boat has drifted from over the rock, and thus the reward, for hours, or it may be for days, of persistent and arduous exertions is lost. And such mishaps must ever continue to recur where two observers are called upon to act quickly and simultaneously under exciting circumstances.

But if in the boat there is only one observer, with a Protracting Sextant, then we may confidently expect that promptness and evenness of action, in observing, under every contingency, which are so essential to the rapid and successful execution of a hydrographic survey.

Although we do not presume to say that the theory of this instrument is so obvious or its manipulations so simple, that "the simpleton, though he run may understand," or that the smatterer and blind routiner (who could not look a quadrilateral in the face without blushing) may manipulate it with ease and accuracy, yet we do not assert without the fear of a contradiction, that to the eye of the ingenious geometer, its theory is most clear, and that in the hands of the hydrographer, who is a master of his profession, this Protracting Sextant will be found the ready and efficient means of determining and plotting, (unassisted and alone) his position, with a facility, ease and accuracy not now attained with two ordinary sextants and one protractor in the hands of two observers and one plotter.

The Santa Barbara Index learns that a movement is on foot there which may lead to the organization of a company for the purpose of building a narrow gauge railroad from Santa Barbara to Panamint and Cerro Gordo, via. San Buenaventura and Elizabeth lake.

LOWRY'S PROTRACTING SEXTANT.

and record them for future reference and closer plotting on the "Office Sheet."

The angles observed with the Protracting Sextant or any other reflecting instrument are measured in the plane of the objects. If this plane be inclined to the horizon and a result rigorously accurate be sought, the angles of elevation of each station above the horizon should at the same time be observed to afford data for reducing the hypsotheneal to the horizontal angle. But this reduction may be neglected in all cases where the difference of elevation of the objects does not exceed two or three degrees and when the observed angle is larger than (the minimum angles allowed in determining a boat's position by observations from the boat), twenty or twenty-five degrees—for, the reduction to the horizon would, in such cases, deal with quantities more minute than the amount of error to which the measures of all angles observed at an unstable station are liable. When the difference of the objects is considerable, an ideal vertical line may be drawn from the highest object downward to an elevation corresponding to that of the lower object, and the angle measured between this vertical line and the lower object—this with some experience and correctness of eye will give results sufficiently near the truth, i. e. within the limit of the errors of plotting. Ob-

of the left hand angle on the right hand limb and the supplement of the right hand angle on the left hand limb—cause the right and left arms of the instrument to traverse points *A* and *C* respectively, and draw a line along the middle arm, then shift the center of protractor, (taking care to keep the points *A* and *C* bisected by the true edges of right and left arms) and draw another line along middle arm and the intersection *J*, of the two lines thus drawn, will be a point on the right line through point *B*, and the required place of observation—draw this line through *B* and *J*, and with the center of the instrument on this line cause the fiducial edges of the right and left arms to traverse *A* and *C*, respectively dot the center and this is the place of observation.

Another method of plotting a position by supplementary angles is to set off the right hand angle on the left hand limb, and the sum of the supplements of the observed angles on the right hand limb of the protractor—cause the left, middle and right arms to traverse the middle, right and left signals respectively—dot the center and it is the required position.

And this instrument also enables the hydrographer and topographer to determine and plot their positions by the two point problem, (in a manner equal in accuracy and second only in point of simplicity to that by the three point

CORRESPONDENCE.

Chrome Ore in Napa County.

EDITORS PRESS:—In Chiles' valley, fifteen miles from Yountville, has been discovered chrome iron containing a very large percentage of chromate of iron. The discoverer brought the ore to Napa, not knowing what it was, or its value. Dr. Boynton, with another party, examined the ore and made a contract with the man for all he could take out, at \$15 per ton delivered at Rutherford station. The cost of hauling is about \$3 per ton. Offers of \$25 and \$30 per ton have since been made, but the contract binds.

With two men he took out some 1,000 tons in a month. The ore would widen out and then as they went down on the ledge would shelve down again becoming narrower until it disappeared entirely. Locations have been made adjoining the discovery. Near the surface some four or six tons will be picked out when the deposit seems exhausted. On going deeper, a small streak will appear, widen out and then narrow down again to nothing.

The discoverer has taken out some fifteen hundred tons, and now the streak of ore is narrowing and disappearing again. Since this discovery several prospectors have brought in specimens of chrome iron from the hills near Napa, having very much the same appearance as this ore from Chiles' valley. I believe that such ore is worth little unless it contains over 60 per cent. of chromate of iron. But even with a higher percentage than that, would the market be unlimited. M. E., Jr.

Napa, Jan. 20, 1875.

Colusa County Quicksilver Mines.

EDITORS PRESS:—Having been a resident of this place for four months, and not having seen a communication from this mining district, I give you a few personal observations. At present we are engaged entirely in cinnabar mining. The old sulphur works have been lying idle since the war prices, as they say the present price of sulphur is not remunerative. Sulphur Creek mining district is situated in Colusa county, upon its extreme west side, and the eastern side of Lake county, thirty-five miles from Colusa. To reach it from your city you can come by rail to Marysville and stage to Colusa; or by rail to Knight's Landing, and boat from there to Colusa. A tri-weekly stage runs from thence to this place. We have also the celebrated Wilbur hot sulphur springs, visited by many and generally found beneficial.

The mines have been operated for years, but principally by men of limited means. During the last year, however, more energy and some capital has given a new start to the district, and capital is looking around for investments. There are at present about 250 miners at work. As you ascend the creek the first croppings that attract attention are those of the Amazon mine, owned by Whitman & Co., of this place. But very little work has been done upon the vein. A quarter of a mile above is the hot sulphur spring and Wilbur hotel. A short distance above is the Oriental mine. One half is owned by Mr. Mahan, of your city, and the other half by parties here. Considerable work has been done upon the mine, showing good ore, and in paying quantities. Next above, and on the same side of the creek, is the Maazanita, owned by Dr. Hughes & Cherry, of this place, but hounded for quite a sum. Considerable work has been done, and good ore is found. It will no doubt change hands. Adjoining above are the Eureka and Montezuma, both showing good ore and owned here.

Further up the creek quite a number of locations have been made, all of which are but little worked until you arrive at the Elgin, three miles above. This is one of the most promising mines of the district. It is owned by Smith, Milburn, and Mrs. Wilbur, all of this place, and Chapin, of Colusa (incorporated). They have a large and well developed vein of cinnabar, and with one retort, 500 pounds capacity, they keep the mine out of debt and work quite a number of miners, making improvements in roads, buildings, etc., and opening the mine. But few mines can show so good a record. Several other locations above show but little work. However, one of our experts, Andy Johnson, has decided upon the richness of that locality and located where promises big results. The Stockton Q. M. Co. have their headquarters there also.

Some three miles to the south of the Elgin is the Abbott mine, located by "Uncle Dick Abbott," a pioneer in the district. It is at present owned by Good, Ingram, Brim, Biddle and others of this county. This is one of the best developed mines in the district. They have a Knox & Osborne ten-ton furnace, and are shipping 20 to 25 flasks per week, and are pushing ahead with the opening of the mine, having good roads, shops, boarding house, and all necessary out-buildings. This is a dividend paying mine, and when depth is attained must be a fine investment.

To the south and on the same vein we have the Excelsior, owned by the Desternell Bros. It has bold croppings and good ore, and is a No. 1 prospect. The next on the same vein south is the General Jackson, owned by Catlin, Msnoh and others here. They are hauling ore preparatory to reducing. The owners look happy and hold "feet" high.

Returning to the creek the first mine on our right is the celebrated Buckeye. Superintendent Casswell who has worked the mine up with flasks for retorts, to small retorts and then to a Knox & Osborne ten-ton furnace, with all necessary improvements. The mine is paying and is incorporated. It is owned Casswell, Smith, Craoston and others here, by Judge Hatch, of Colusa, and Belcher of Marysville. Like all other mines here as they go down the ore body increases in quantity and quality.

Next down the creek is the Empire with fine prospects, and no doubt one of the first-class mines of Sulphur creek. Owned by Van Winklo, Perdue, Furth, Seube, Sr., Belton and others all of this county.

The district is at present shipping 50 to 75 flasks mercury per week. This is certainly one of the rich cinnabar districts of the coast and ere long must attract capital to it. With that, in a very short time, the shipments of mercury would astonish the outside world. There are many other locations in the district that I may notice at another time.

RAMBLER.

Sulphur Creek, Colusa county, Jan. 20, 1875.

The California Blue Lead in Oregon and Washington Territory.

EDITORS PRESS:—In the early days of "forty-nine and fifty," the miners were of the opinion that when the rivers, creeks and ravines were worked out that the placer mines of California would be exhausted, but such is not the case, for since that time there has been another class of mines discovered, commonly called the deep gravel mines, of which the "Blue Lead" is the most extensive and profitable. This lead was discovered first at Minersota, in Sierra county and was traced north across the entire county to Feather river, where the miners lost all trace of it. The reason of their not finding the lead farther north was this: As far as the miners traced the lead its course was due north and south, but at Feather river it takes a turn and runs northwest through the mountains, close to Lassen's Butte, thence to Shasta Butte, thence to Cottonwood and Jacksonville in Oregon.

In 1857, accompanied by four others, I left Yreka, Siskiyou county, to see if we could find any traces of that famous Blue Lead. We were all aware, however, of the existence of a gravel lead between Cottonwood and Jacksonville, but the lead, on the surface, was so unlike that of Sierra county, that we were of opinion that it was a different lead. But in the course of our travels we came across a gravel lead in all appearance the same as that at Cottonwood. We then turned south and followed it through the mountains, until we reached Feather river traveling due southeast, and to our surprise we found the identical lead connected with the Blue Lead, leaving a space from Cottonwood to Feather river unprospected for that famous Blue Lead.

Various are the opinions pertaining to the gravel, it being found so high, even on the tops of the highest mountains. The prevailing opinion is that it is from a river that flowed from north to south. Such is also my opinion from the fact that it has a rim to it. The rim is the bedrock projecting out on the side of the mountain, and then pitching back into the mountain or deep channel, commonly termed the pitch of the rock. The miners have to tunnel through it to drain their mine. In some places the miners have tunneled 2,000 feet before striking pay ore.

This lead has been found in Sierra county, and extends north and south the entire length of the county. In Nevada county it has not been so extensively worked or identified, but the miners have worked several other beds of quartz gravel, all the off shoots of the Blue Lead. This lead is about 1,000 feet wide and must be tunneled and drifted. Those in Nevada county are principally worked by hydraulic washing.

In 1870, I again resolved to extend my explorations for the Blue lead into the State of Oregon, so in the month of June in that year, I crossed Rogue river, about seven miles above Jacksonville and ascended the Cascade mountains on the east side, and when to within 500 or 700 feet of the summit, I could see here and there some smooth quartz gravel. I then started north on that level, parallel with the mountain, and when about 30 miles from Rogue river I found a quartz gravel bed, in all appearance the same as that I traced through California.

I continued my travel parallel with the mountains until I reached Mount Hood, finding the gravel the entire distance, and when near Mount Hood, I looked through my glass off into Washington territory, and I could see the same class of land marks that have guided me through California and Oregon.

I then resolved to explore Washington Territory the following summer, so again in 1871, I crossed the Columbia river at Umatilla and started on an Indian trail for the head of the

Yaquina river, where I had no trouble to find the gravel bed, I then started north to follow it, until I reached the British Columbia line, and not wanting to explore any other than Uncle Sam's domain, I then turned back designing at some future time to write out the foregoing.

Since writing the above my mind has wandered back to my several explorations, and I have come to the conclusion that the discovery of the Blue lead, or ancient river bed, to the extent as above stated will be, or will lead to the grandest geological discovery that ever will be made in the mountain ranges of the Pacific coast, and I here state, that I am ready at any time to be the "Kit Carson" should there be any party of scientific gentlemen who desire to explore and investigate the above statement.

ANDREW CASSEIDY, "Mountaineer."

Virginia, Nevada, January 22d, 1875.

STRUCK PAY.—The Mountain Messenger (Sierra county Cal.) Says: It gives us great pleasure to record the fact that the owners of the Iowa gravel claim, located near Mt. Pleasant ranch, on the road from Port Wine to Seales Diggings have, after many years of patient labor, struck a fine bed of blue gravel which prospects exceedingly well. Several years ago, just how many we do not remember, the company commenced sinking a shaft on their claim, said shaft being put down 180 feet, but not without several stoppages, owing to want of means. Gravel was at last reached, and it was thought of sufficient richness to warrant the running of a long tunnel which tapped the shaft at the depth it had then reached. When the tunnel was completed it was found that the gravel, though fine looking, would not pay for drifting. The owners, from lack of means, being all poor men, were compelled to quit work, and the claim was allowed to lie idle for a year or more. Last spring work was again resumed. In the bottom of the shaft the bedrock was found pitching away under the hill, which proved they were on the rim of the channel. A tunnel was started from the bottom of the shaft, and pushed a distance of 300 feet with a grade of two feet. At that distance they thought they must be over the channel, and sinking a shaft to the depth of 55 feet struck rock and found excellent pay. The perpendicular depth below the engine house at the mouth of the shaft, at which pay was reached, 233 feet, and still, judging by a diagram sent us by our old friend, John P. Lloyd, Secretary of the company, the bottom of the channel has not yet been reached, the bedrock still pitching away from them into the ridge. The character of the deposit is the genuine blue gravel, and every indication is that an immense channel has been tapped, and one that will equal in richness any of the blue gravel leads of California. We sincerely hope that the Iowa boys have secured their fortune. If the lead develops as well as it prospects, it will stimulate prospecting in that section, and prove that it is one of the richest portions of the country.

WEBB'S FLANGERS.—Yesterday afternoon we accepted an invitation to ride on one of the flat cars to which was attached a flanger, an invention which clears the ice and snow from the rails in a neat effective manner. This invention is due to Mr. Nate Webb, who has won a well deserved fame as the chief of the snow plough department of the Central Pacific railroad company, and it promises to work a revolution in the manner of keeping the rails free from ice and snow.

The flanger cuts and clears away the ice and snow to the depth of two inches on the inside of the track, and about three-quarters of an inch on the outside, thus giving a perfect rail to drive wheels on the outside as well as on the inside. It does the work very satisfactorily and it promises to take the place of the pick and shovel as instruments for flanging the railroad track. It will do the work of a thousand men with pick and shovel and has this other advantage that it can be sent ahead of a train and give it a perfect track without delay. The way it sends the snow and ice flying is a caution. It is attached to a flat car by four bolts, and can be removed or adjusted in twenty minutes. Every one that sees it testifies for its usefulness, and says that there is a sure fortune in it for the inventor.—*Truckee Republican.*

SOMETHING NEW.—Capt. Taylor, superintendent of the Yellow Jacket mining company, will introduce a new feature in mining machinery in ventilation. He has returned from the Bay and has brought with him a new fan or blower, together with a small turbine wheel of about two feet in diameter. These he will erect in the 1500-foot level in the incline, using the wheel, which will be fed by the water running down the incline, to work the blower on the 1500-foot level of the Yellow Jacket, a drift connects with the Crown Point, from which proceeds a good draft. The blower, which will be operated by the turbine wheel, it is calculated, will save 500 feet of air, and greatly benefit the miners working in the lower levels. We hope to hear of the success of Captain Taylor's experiment.—*Gold Hill News.*

The Columbus mill and mine, of Esmeralda have been sold at an assignee's sale for \$13,000. This sum is only a tithe of its indebtedness. One mortgage is for over \$26,000, and the small claimants are legion.

The Panamint News rejoices at the fact that Jones & Stewart, of the Surprise Valley mill and water company, have discharged all the Chiuamen in their employ and their places are to be supplied with white men.

Cinnabar in Trinity.

We make the following extracts from Trinity county Journal in relation to the cinnabar interests:

Within a couple of years developments have been made which show that our county has element of wealth which has thus far lain dormant, but the production of which will take its place among the leading and permanent industries of the county. We allude to the cinnabar discoveries, first made three years ago, but only lately tested to an extent to testify us in believing that within our territory limits some of the richest mines of that which the world can boast of are to be found. Within a few years quicksilver has so advanced in price that it may almost be reckoned as one of the precious metals.

The constantly increasing demand for quicksilver, combined with the high price it commands, stimulated prospecting to a great degree, and has resulted in the discovery of a number of mines of more or less value. The new discoveries have had little or no effect upon the market price of quicksilver, and article of commerce is held at a figure twice as great as the ruling value five years ago. The western slope of the Sierra Nevada contains gold in abundance; on their eastern slope, through the mountains of the deserts of Nevada, mines of silver abound, and it was served for the Coast Range to furnish deposits of quicksilver so necessary to successful and remunerative working of more precious minerals. Napa, Lake, Colusa and Mendocino counties have each in turn furnished the field of enterprise for energetic prospectors, and their labors, to certain extent, have been repaid. Their discoveries created quite an excitement; not great a one, indeed, as followed the rich silver discoveries, but, for a time, the counties have named were thronged with prospectors eager in the search for indications of that which has of late years assumed such a prominence. Our own county was last among them in which prospecting to any extent was undertaken, but the present indications are that will soon take rank as the leading quicksilver producing county of the State.

The existence of rich deposits of cinnabar in this county has long been suspected. From almost the earliest days of mining on Trinity river, the presence of small particles of mineral was noted, though what it was was a great extent unknown. The small particles were difficult to separate from the fine dust, and nearly every ounce of dust washed out by the old-fashioned methods of the roasting and sluicing contained more or less cinnabar. When found on the low river bars the particles were small and solid—those found in the hills and benches were larger in size and more easily pulverized. In heating the gold to melt it, it would be observed in the dark that particles buried with a blue flame; and it was also noticed that the cinnabar was thicker the gold washed out of "top" gravel than that taken from strata near the bedrock. Since the search for the more valuable mineral, the constant presence of cinnabar was overlooked, or dismissed with a passing comment; and it was not until a few years ago that prospecting for the source of this supply was inaugurated, with what promises to be the most happy results. It is found in a part of the country remote and difficult of access, and this fact, together with high altitude at which they are situated, making the working season very short, has materially retarded their development. We have no disposition to magnify or overrate the extent or value of our cinnabar deposits, but the counts which have come to us from reliable sources warrant us in the belief that the large and permanent manufacture of quicksilver will, long, become a permanent and leading industry of the county.

BLUE TENT.—There are at present but two mines at work at Blue Tent—the Blue Tent and the Sailor Flat. The former mine is run by five machines and using 1,500 inches of water in 24 hours. The latter uses 500 inches one motor. The water used at the Blue Tent mine is obtained from the South Yuba canal company, and from summer ditch owned by the company. A ditch was commenced last spring which will, when completed, afford a supply the year round. It commences at the Yuba river above Culbertson's bridge opposite Emigrant Gap. It will be 27 miles long. Over half of the labor and cost has been expended. The heavy fluming and tunneling has been completed. There is one tunnel 1,000 feet long, which cost \$6.50 per foot, another 300 feet long which is about half completed at a cost of \$3.50 per foot. The ditch will be completed in the early summer. It might have been done now with the work which has been expended by running around hills with flumes, but it would have been less permanent. C. W. Tozer is the superintendent, to whom we are indebted for above items.—*Nevada Transcript.*

A large boiler is being made by Moynihan & Acken for the steamer, Wm. Taber, weighs nearly 90,000 pounds; it measures sixteen feet in width across the front; the height, including steam chimney, is twenty-five feet, nineteen feet; and diameter of shell fourteen feet eight inches, all of the very best of iron, three-eighths of an inch thick.

The mining intelligence from Cariboo is considered very favorable.

MECHANICAL PROGRESS.

Foundry Economy.

a lecture on "Applied Mechanics," (in England, some time since), Mr. John Anderson, C. E., after familiarly describing the distinctive properties of cast and wrought iron, speaks of the molecular structure of cast iron. All metals, he said, are crystalline, the crystallization is better observed in some than in others. In cast-iron, especially, it is very apparent. The crystallization of cast iron is governed by a natural law. This law was first pointed out, to the best of his belief, twenty years since, by Mr. Mallet, and is this: In cast-iron is in a liquid state—when the scales have sufficient heat among them to give liquidity—the direction of crystallization is determined by the lines into space which the scales take. When this law was first stated, it received with skepticism, but ever since law had been pointed out, he (the lecturer) never observed in any piece of broken cast iron an example to the contrary. If we introduce into castings irregularity of figure, or anything which creates currents outward, in various directions, then we get wrong; we introduce lines of weakness. According to this law, gains up to this time have always been wrong. The Americans are acting upon law in every thing they are doing, and that of theirs, which some time back came to this country, almost like a soda-water bottle in shape, was constructed in strict accordance with this law, and, therefore, possessed the utmost strength attainable with the same weight of metal. The molecular appearance of cast iron depends on the rate at which the heat is taken out of the casting.

As to the goodness of cast-iron, goodness for all castings is not goodness for a hydraulic cylinder; goodness for a hydraulic cylinder is goodness for a gun. Density is a quality required for both the latter, but we don't want density for a hydraulic cylinder, but for a gun we require very great density. As a rule, the hardness of cast-iron or cast-steel depends upon three things: First, on the quantity of carbon which the mass contains; second, on the heat which it was raised before carrying the heat out of it; and third, at the rate at which that heat is hastened out of it. All these conditions determine the character which cast-iron or cast-steel assumes. In casting iron in moulds, where hardness is wanted, some method is adopted so as to carry the heat out rapidly; where softness is required, means are taken to carry the heat out slowly, and it does not matter what the method is so long as it is effective. The hardness of steel depends on the quantity of carbon which it contains, and on the rate at which the heat has been taken out of it. After allying at some length to the founder's art, the lecturer proceeded to speak of the casting of a fly-wheel, stating that the only thing which would serve such a casting intact while cooling, is to take care that every part should cool at the same rate. The arms, being least in substance, would naturally cool first, but they must be kept hot by covering them with fire, or by other convenient means. If we require a particularly good casting it must be cooled slowly.

Many of the difficulties of the caster would be got rid of if we could prevent the formation of gas within the mould. The Americans are very much more careful in this respect than we are, and this is the explanation of their castings standing so well. Mr. Babbitt uses fire-bricks, which after, say, ten years' service, have not changed color; any fire-bricks that are discolored he rejects. He grinds these to a powder, and thus gets a perfectly pure and refractory material for his moulds, using pipe-clay, the best material for the purpose, to render it adhesive. The mould is first made red-hot, and this red-hot mould then receives the metal. Not a particle of gas is generated by the mould. Another American founder, Mr. Rennie, uses Kaolin, which he obtains from England (Devonshire), and treats it in a similar way to that in which Babbitt treats his powdered fire-bricks and pipe-clay. To show the earnestness of our American competitors—and we shall have them as competitors—they resort to the method of taking the heat out of the castings in the way least injurious to them. They try to establish the conditions of a built-up gun in a cast-iron one, to have every atom of the gun under tension. We English, as a people, must pay the same attention to natural laws as the Americans and French are doing.

ENGLISH RAILROAD IRON.—The importation of English railroad iron into the United States is falling off at a rapid rate. The average monthly importations for 1872 was 37,000 tons; for 1873 it was 15,000 tons; while for 1874 it has fallen to 9,000 tons. America is now nearly independent of Great Britain in the iron trade, and will soon prove her powerful competitor in foreign markets—British iron masters see this, and are seeking to save themselves by establishing free trade between this country and Canada, and establishing branch manufacturing in that province.

SUPERIOR STEEL.—By means of one or two processes now in vogue in some of the European workshops, says a contemporary, an article is produced equal, in all respects, to the celebrated Damascus iron and steel of antiquity.

Metallic Contraction.

The following from Pynchan's Chemical Forces, although published some time since, will be found peculiarly interesting:

The force of contraction is equal to that of expansion, and quite as irresistible. Its immense power was strikingly illustrated some years ago in Paris. The two sides of a large building, the Conservatoire des Arts et Metiers, having been pressed out by the spreading of the arched ceilings and the immense weights supported by the floors, M. Molard undertook to remedy the evil by boring holes in the wall at the base of the vaulted ceilings, and opposite to each other, through which strong iron rods were introduced, so as to cross the interior of the building from one side to the other. On the projecting ends of the bars on the outside of the building were placed strong iron plates, which were screwed, by means of nuts, tightly against the walls. The rods were then heated by means of rows of lamps placed under every alternate bar, and being lengthened by the expansion, the nuts and plates were pushed out to the distance of an inch or more beyond the wall. While in this condition, the nuts were screwed a second time tightly against the wall. The lamps were then extinguished, and the rods, contracting as they cooled, drew the wall together with a force almost irresistible, and to a distance as great as that to which they had been lengthened by expansion. These bars being then left in their new position, the alternate bars, which had remained unheated, and by the contraction of the others had been also made to project beyond the walls, were again tightly screwed against the building. These were in turn expanded and lengthened by the application of the lighted lamps, and once more screwed up tightly against the walls. The lamps were then extinguished, and by the contraction of the second set of bars the walls were drawn still further toward each other. These were then left, in turn, to hold the building in its new position, and the first set of bars was again brought into requisition. And thus the process was continued until the walls were drawn into their proper vertical position; and the bars being left in their places, they have remained firm and upright ever since. In this manner a force was exerted which the power of man could scarcely have applied by any other means. The same process has since been applied to the restoration of other buildings which were threatening to fall.

IMPROVED TUYERE FOR FORGES.—We find in the English journals, the following notice of a paper read by Mr. W. Smyth, before the British Association, which described a very simple but important improvement in Smyth's forges, by which the forge is much more fully under the control of the workman, and by which the life of the tuyere is greatly prolonged, the work of heating the metal more uniformly and uninterruptedly carried on, and a great economy of fuel effected. A cast iron trunk or box is placed horizontally from the back and front of the forge. The front end is closed by means of a slide or door. The back end has a hollow tower which rises above to a suitable height, and upon which is fitted a cast iron tuyere block with, by preference, two long slot holes for the blast. Within the trunk is a long lever working in an axle or spindle, which at its longer end has two punches which rise vertically, and are from time to time projected through the slots to displace the slag and keep the tuyere openings clear. This the workman does, by moving a lever upon the outer end of the spindle or fulcrum of the levers. The iron trunk or box becomes heated by the surrounding fuel, and utilizes the heat, which would otherwise be wasted; thus effecting a considerable economy of fuel by heating the air of the blast.

THE FIRST PLANING MACHINE.—The first planing machine ever made was, according to the London Iron Trade Exchange, constructed in the Holland street works of John Rennie the elder. "In March, 1814 (and we copy from an original memorandum book of the late George Rennie), the following plan was adopted for 'chipping' the cast-iron sides of a new lathe. The sides are placed close together, with their faces upward. Two planks of elm, one on each side, are bolted with their edges truly placed end upward. Upon the edges of the elm planks run four wheels on axles, which support a truck of oak. To the truck is fixed a slide rest, to which is attached a cutting tool. The truck is well loaded with weights, and pulled along the surface of the elm planks by means of a crab and chain. Thus the tool, in fact, planes the iron lathe-beds straight." This was in fact the first planing machine, crude and rude as it was, and from it Whitworth, to whom the original apparatus was shown subsequently made a self-acting machine. We all know how important a tool it has become, and the wondrous saving it effects in the manufacture of nearly every kind of machinery.

LARGE HAMMER AND CRANE.—The largest trip-hammer in the United States has recently been completed at Nashua, New Hampshire, at an expense of \$75,000. The weight of iron in the machine is about 200 tons; the rams weigh 12 tons; its striking force is about 100 tons; and four large boilers are brought into use to furnish steam to run the 600 horse-power engine required to work it. The immense crane with which the iron that is being manipulated is hoisted into position is the largest in the country, and is rigged with modern mechanism so nicely that two men can easily hoist 50 tons dead weight.

FILE CUTTING MACHINERY.—Dr. G. Haseltine, of Southampton-buildings, London, has taken out a patent for machinery for cutting files. The invention relates to a file cutting machine in which a bed is used that rests directly upon the feed screw, the said screw being of sufficient strength to support the bed while the file is cut. The feed-motion of the screw is produced by a ratchet wheel and pawl, and with these parts is combined a spring which acts on the cover of the journal box, at one end of the feed screw, the cover being supported by an eccentric. The bed is saddle shaped, and with it is combined a frame with parallel motion links, for the purpose of lifting the bed out of gear with the feed screw. This bed is provided with a cavity to receive a semi-cylindrical secondary bed, and with these two beds is combined a gauge, which bears on the secondary bed and maintains the surface of the file blank parallel with the edge of the cutter. The file blank is retained on the secondary bed by clamping jaws and a spring. The stock which carries the cutting tool moves between guides or slides, which can be set to insure accuracy in the movement of the cutter. The tool stock is operated by compressed air.

TROWING WATER FROM PIPES.—Experiments made at the Holley water works in the town of Lake Michigan, shows that a pressure on the service pipe of 109 pounds to the square inch will force water to an elevation of 120 feet through a fire hose. The same experiments also proved that while the water pressure at the engine, eight miles distant, was 129 pounds, it stood at 109 pounds in town. This seems to be a very small waste of power in conveying water eight miles. If the report is correct, the fact is important.

SCIENTIFIC PROGRESS.

Science and Faith.

Professor Tyndall lately gave the first of a series of six popular science lectures at the Free Trade Hall, Manchester. The subject was "Crystalline and Molecular Forces." Toward the close of the lecture, after a successful experiment showing the tendency of atoms to follow an architectural instinct, he said although he had seen this experiment hundreds and hundreds of times, he had never looked upon it without feelings of astonishment. The revelations of science were not in the least degree calculated to lessen one's feelings of astonishment. We were surrounded by wonders, by mystery everywhere. He had often in the spring time watched the advance of the sprouting leaves, and observed the general joy of opening life in nature, and had asked himself this question: Can it be that there is no being or thing in nature that knows more about these things than I do? Do I in my ignorance represent the highest knowledge of these things existing in this universe. The man who put the question fairly to himself, if he were a man capable of being penetrated by a profound thought, would never answer that question by professing that creed of atheism which had been so lightly attributed to him. "It is not," Professor Tyndall said, "always those who are charged with skepticism who are the real skeptics, and I confess it is a matter of some grief to me to see able, useful and courageous men running to and fro upon the earth wringing their hands over the threatened destruction of their ideas. I would exhort them to cast out skepticism for this fear has its root in skepticism. In the human mind we have the substratum of all ideals, and as string responds to string when the proper note is sounded, so surely, when words of truth and nobleness are uttered by a living human soul, while these words have a resonant response in other souls, and in this faith I abide, and in this way I leave the question."

TIDES OF LAKES AND LAKELETS.—It is said by most authors on tidal theories that there can be no tides on lakes, for the reason that the moon's attraction is equal over the whole surface of water. I hold that there is a tide raised from every body of water on earth. It is impossible for the moon to raise a body of water from the earth by its attraction, but it counterbalances or neutralizes a portion of the earth's attraction for the water, in consequence of which the water becomes lighter, and the lower portion not so much compressed. Hence, on account of the elasticity of the compressed water, the diminution of compression is followed by an expansion which drives the superincumbent water upward. This is a natural principle which belongs to all bodies of water, although the effect is imperceptible if the water be shallow and not connected with very deep water.

By this theory I account for the very considerable tide that rises on Eagle Lake in the northern part of California. The lake is very deep and has never been fathomed.—*Cor. Scientific American.*

FALL IN THE VALUE OF AMETHYSTS.—According to the *Journal of Applied Science*, the large number of diamonds that has been thrown into the market since 1872, from Brazil, has caused a great depreciation in their value. The first lots sent to Europe brought from \$500 to \$600 per araba of 32 pounds weight; but as the quantity increased the price rapidly receded, and at last finally decreased to nothing. At present no offer can be obtained for any lots on hand.

Use of the Spectroscope in Puddling.

Mr. A. McMartin recently stated, at the American Institute of Mining Engineers, that the use of the spectroscope in the Zwickau process was one of the most beautiful experiments in metallurgy.

He says that one never tires watching the brilliant changes in the spectrum, blow after blow. The specific causes of these changes have been the subject of much dispute and unsatisfactory investigation. But all are agreed that carbon has something to do with them, whether as such, or in gaseous form in such nitrogenous compounds as cyanogen. Whatever be their cause, these changes do take place—and that so regularly that an experienced eye can place full dependence upon them as indications of the state of preparation of the metal bath. The spectrum at first appears without lines; but as soon as the spark period begins to give place to its successor, and the clear flame to extend out of the mouth of the converter, the bright orange yellow sodium line quickly makes its appearance, and remains clearly visible till the blast is turned off. After the sodium line appear the red lines, which represent calcium lithium; and then a beautiful series of perfectly graded green lines in the green, and pale blue lines in the blue section of the spectrum, manifest themselves, one after another, each in its series, until, at the climax of the operation, when the greatest heat is attained, the spectrum rivals that of chloride of copper in beauty and brilliancy. A very experienced eye can also see a beautiful violet line in the violet section at this point.

But the characteristic lines of the Bessemer spectrum are the beautiful, band-like, graduated series in the blue, and especially in the green section. In the inverse order to that in which they arose to their climax, these lines gradually diminish in brilliancy, and at last vanish. But some of the green lines still remain, after the blue series has entirely vanished; and at this point nothing must be allowed to distract the conductor of the operation from closely watching the spectrum; for the only index (though a perfect one) of the exact end of the operation, is the degree of brilliancy of certain green lines, which remain when the charge has arrived at the point of desired decarburization. For different mixtures of pig iron a slight difference in the appearance of the indicating green lines is noticeable at this point; and to secure with the same mixture a desired slight difference in the character of the steel produced in two different blows, proper allowance must be made, on the other side, of a certain degree of brilliancy of the green hues.

SEWAGE UTILIZATION.—Recent investigations have raised grave doubts as to the propriety of using sewage as a manure, the vegetables raised by its means proving unhealthful. If we can light our streets and houses with the contents of the sewers, the great problem of what to do with the sewerage of great cities is in a fair way to be solved, but it will not do to be too sanguine. In this connection we may call attention to a ridiculous paragraph which has recently found its way into the public journals to the effect that an English inventor is making an illuminating gas from sewage water. It is said that forty-seven feet of gas is obtained from one quart of sewage water. One foot of sewage gas gives as much light as three feet of coal gas, and the flame is much clearer, purer, more healthful, and cheaper. The process consists in passing the liquid through two heated retorts, then through an iron cylinder called the hydraulic main, which is above the furnace, then through another heated retort, and next through a coil of metal piping immersed in cold water. Afterward the process is the same as in making coal gas.

BURIED KNOWLEDGE.—It is impossible to foresee to what extent scientists of our time will resurrect the buried knowledge of the past. The bricks of Nineveh, stamped with unknown letters in an unknown language, have been deciphered and translated; the existence and manners of the men who lived contemporaneously with the elephant and rhinoceros in Europe have been inferred from fragments of bone and stone; the domestic religion of the early Greeks has been explained for the first time after a lapse of 2500 years; and now we are about to have a translation of a comprehensive treatise on medicine, as understood and practiced in the valley of the Nile 3400 years since. A large papyrus, written in hieroglyphics and in excellent preservation, found in a pyramid, has been translated in Europe, and is now being printed by steam to satisfy the doctors that their learning and their ignorance do not date from yesterday.

IMPORTANT DISCOVERY IN LUBRICATION.—Professor Barker, of Philadelphia, and formerly of Yale College, has recently made a discovery which promises to be of great value to railroad men. It is a metallic paint, intended for application to "journal boxes" on railroad cars. The paint when heated to about 160 degrees Fahrenheit turns from its original color, which is a deep clear red, to a pure black, and immediately on cooling it resumes its redish hue. The journal boxes being covered with this paint, train hands detect at a glance whether a journal has heated or is heating. Their knowledge now is only gained when the wood work is ignited, and the damage has already been done.

Mining Stocks.

The bottom has apparently dropped out of stocks and everything is at "bed rock" prices. Even the big bonanza mines have had spots knocked out of them, and are down at the bottom of the ladder. All animation has departed from the stock market, and with the depression in prices the buyers are fewer. The news from the principle mines on the Comstock is as favorable as ever, there being no noted indications that the big mines are any poorer than they were a few weeks ago. Neither is there any indication that some of the little mines are richer, as the falling off in prices would seem to indicate, according to the rule of late. How long the present depression will last, it is, of course, impossible to state. The difference in prices between stocks this week and last, can be seen by our stock table.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's Office at San Francisco:

INDIAN QUEEN M. AND M. CO., Jan. 21.—Location: Emeraldal county, Nevada. Directors—A. E. Davis, Seth Cook, Edward Barron, Grove Adams and Wm. Adams. Capital stock, \$6,000,000, divided into 60,000 shares.

NORTH SAN FRANCISCO S. M. CO., Jan. 21.—Location: Storey county, Nevada. Directors—A. Staples, C. J. Eaton, C. M. Peck, C. J. F. Atwell and H. R. West. Capital stock, \$10,000,000, divided into 100,000 shares.

HOPE QUINCY MINING CO., Jan. 21.—Location: Sonoma county, California. Directors—Thomas Hardy, Edward McLean, Jacob Hardy, S. W. Howland and W. P. Morey. Capital stock, \$5,000,000, divided into 50,000 shares.

GOODALL, NELSON & PERKINS STEAMSHIP CO., Jan. 22.—Objects for which the corporation is formed are, the transaction of the business of a steamship company on the Pacific Coast, and in any of the ways or harbors thereof, and anywhere in the Pacific Ocean. Also, the carrying on of the business of warehousemen and wharfingers in connection with said steamship company. Directors—Charles Goodall, Christopher Nelson, George O. Perkins, John O'Farrell, John Rosenfeld, F. S. Wiegner and Edwin Goodall. Capital stock, \$2,000,000, divided into 20,000 shares.

WELLS-FARGO MINING CO. OF CALIFORNIA, Jan. 22.—Location: Storey county, Nevada. Capital stock, \$10,800,000. Directors—D. L. McDonald, C. R. Johnson, A. C. Taylor, H. Z. Wheeler and George W. Hammer.

NORTH CONSOLIDATED VIRGINIA M. CO., Jan. 22.—Location: Virginia mining district, Storey county, Nevada. Capital stock, \$10,000,000. Directors—H. P. Wakelee, Robert C. Rogers, E. M. Fry, N. B. Stone and George W. Hopkins.

ALBANY QUICKSILVER M. CO., Jan. 22.—Location: Lake county, California. Capital stock, \$6,000,000. Directors—R. W. Tully, C. N. Toser, E. G. Waite, William U. Young and J. G. Kiley.

SENATE No. 1 or PATENT MINERALS, Jan. 27.—The purposes of the organization are to deal in real estate, mining stocks, and anything else for which individuals may lawfully associate themselves. Capital stock, \$10,000,000. Directors—J. W. Rimington, Uriah B. Thomas, Charles C. Terrill, Frank D. Morrell, and A. M. Winn.

The Union Consolidated silver mining company has filed a certificate of increase of capital stock from \$2,000,000 to \$10,000,000.

The Buckeye silver mining company on the 20th, increased its capital stock from 16,000 to 48,000 shares.

THE LAIRD MINING COMPANY. Object: Carrying on

MINING SHAREHOLDERS' DIRECTORY.

Compiled every Thursday from Advertisements in the Mining and Scientific Press and other S. F. Journals.

MENOCINO M. CO.—Location: Mendocino county. Capital stock \$100,000, in shares of \$20 each. The following companies have filed certificates of increase of capital stock:

CONS. VIRGINIA M CO. from \$10,800,000 to \$54,000,000 in shares of \$100 each.

CALIFORNIA M. CO. from \$10,800,000 to \$54,000,000 in shares of \$100 each.

GOLD & CURRY M. CO. from \$4,800,000 to \$10,800,000 in shares of \$100 each.

SUCCOR M. & M. CO. from 22,800 shares to 68,400 of \$50 each.

Meetings and Elections.

The following mining companies have elected officers for the ensuing year during the past week:

NORTH CALIFORNIA G. & S. M. CO., Jan. 25.—Directors: C. B. Greathouse, J. H. Blood, S. Franklin, W. H. Aitken, and J. K. Laska.

LYON M. & M. CO., Jan. 27.—Trustees: F. Birdsell (President), Henry F. Stone (Secretary), and John Scott and Edward F. Stone (Secretaries). The company paid two dividends of \$20,000 each during the fiscal year, one in April and the other in July. The works of the company are at Dayton, Nevada, and consist of large buildings, mills and other improvements, and considerable custom work is done.

BONANZA M. CO., Jan. 25.—The following officers were elected: F. B. Horton, President; C. F. Hurley, Vice-President; John M. Johnson, Treasurer; F. Madge, Secretary, and D. G. McLaughlin, General Superintendent.

CALIFORNIA M. CO.—Trustees: Edward Barron was elected President; Charles H. Fish, Secretary, and Edward Barron, J. C. Flood, W. S. O'Brien, S. Haydenfeld and T. H. Williams, Trustees. The balance sheet shows the company's indebtedness to be \$80,500; expenses last year, \$78,812.41; cash on hand, \$1,087.86.

KOSSUTH M. CO.—Trustees: A. F. Everett, Robert Sherwood, J. E. Shawhan, Peter Thompson and M. Hochstetler were elected. The company was continued as Secretary, and P. H. Scott was chosen Superintendent.

RAYMOND & ELY M. CO., Jan. 26.—Trustees: Alpheus Bull (President), R. F. Morrow, Geo. W. Haver, A. K. P. Harmon and Henry Raymond, T. W. Colburn, Secretary and H. H. Day, Superintendent.

BELORES M. CO.—Trustees: J. D. Fry, President; A. K. P. Harmon, Vice-President; J. H. Dohinson, R. F. Morrow, B. F. Sherwood, H. C. Kibbe, Secretary and William H. Smith, Superintendent.

MINING SUMMARY.

Following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

VERAS COUNTY.

CAVALERAS MINE.—*Calaveras Chronicle*, Jan. 23: Work is progressing favorably in the San mine at Railroad. The main shaft is deep, and levels are now being run. It is thought the lode will widen as the levels are run, and very favorable developments are expected in the near future. No other district is more energetically and vigorously worked than the Sanderson, and there is one that gives better promise of permanent and valuable.

The temporary interruption of the mine, resulting from the late heavy rain, is now over, and operations are going on. The shaft is free from water, and work of running the 1000-ft level is going on. The batteries continue to find metal in crushing rock from the 900-ft level.

REPAIRED.—The damage to the ditch Canal and Mining Company, resulting from the late storm is repaired, and a full water again running. The break was by land slides—avalanches of soil slipping down the steep hills into the ditch below. It is not probable that either miners or stock will have to mourn the scarcity of grain this season.

HILL MINE.—The new company has taken hold of the Prussian Hill mine, and is pushing operations forward. The main shaft is down 225 ft, and at this point the developments are of the most encouraging character. The company is determined to thoroughly prospect the mine, and the object in view will continue sinking. It is supplied with good machinery.

COUNTY.

MINES IN SCOTT'S VALLEY.—*Lakeview*, Jan. 28: In November, last year, J. H. Hunter discovered a lode of mineral in the hills bordering Scott's valley, five miles northwest of Lakeport. Having started at mining both in California and in Nevada, Mr. W. was pretty confident that the silver-bearing in character, so he sent men from the surface to San Francisco, Cal. The return received gave \$97 in value to the ton. A subsequent assay made by Whitton at Ukiah, by mill process, gave the ton of rock from the outcroppings of the same mine, which is named the "Emigrant." Three other mines, the Mountain, the Manzanita and the Morning Star are in the vicinity, all of which show silver rock. The ledge are from four to 20 ft thick. The miners have organized and their locality the Blue Lake District. H. Wattenbarger has been elected assessor.

DA COUNTY.

YORK HILL.—*Foot Hill Tidings* Jan. 30: Work of rich ore still continues in this district and if anything gets better. Superintendent has his hands full of rich specimens every time he comes up. The ledge is three feet thick and it all contains gold and silver fully up to bonanza standard. The Rocky Bar, Allison Ranch, Gold Hill, and scores of others which are in the vicinity, all of which show silver rock. The ledge are from four to 20 ft thick. The miners have organized and their locality the Blue Lake District. H. Wattenbarger has been elected assessor.

Work is going on in many places here just now. We strolled over the hills in all directions this week and found new veins to the surface in a great many places. This is as it should be, and we hope to be able to note a good many rich veins here, heretofore, nothing encouraging has been brought to light.

Lucky mine and the old Cambridge, now belonging to one company, are being worked under charge of Capt. J. White, the superintendent. A shaft on each of these has reached the ledge and the quartz is being worked. The company which we have known as the Howard Hill, except to stop their mill and to produce gold bars as a spring as a supply of wood can be obtained. This will put life into the long deserted village of Union Hill.

ROBBING.—*Nevada Transcript*, Jan. 23: The Holme mine at Scott's Flat was visited by robbers on Wednesday night, and a box at the head of the flume was cleaned up. Mr. Holmes thinks it has been done early Thursday morning, and it was traced by their tracks to an old mine where the amalgam had been burned. A fire still burning in the cabin. Mr. Holmes came immediately to town, and found \$50 worth of gold which had evidently been taken from an above, had been sold at the store. It is supposed that between three and four hundred dollars in all were taken, besides a tank of quicksilver.

There is in the mine hereabouts have been very busy keeping down the water, but are found equal to the task, and every day is a lovely now.

JUAN ITEMS.—*San Juan Times*: We read Mr. Burns, of Malakoff, that the ditch, the Eureka lake ditch, and the Bloomfield ditch are broken in many places between here and Eureka. It is impos-

sible now to make even a guess at the amount of damage resulting from the late storm.

The Eureka lake company's mines at North Columbia are in full blast. They have plenty of water and are breaking rich ground.

PLUMAS COUNTY.

NORTH FORK ITEMS.—*Plumas National*, Jan. 23: Surveyor Keddie, who has been at work for some weeks over in the North Fork country, returned on Sunday last, and kindly furnishes us with the following items: The recent trial of the North Fork Company's big pipe demonstrates to a certainty that it will prove a grand success. Five hundred inches of water went through the pipe with only a "head" of thirty feet—that is, the water only backed up thirty feet higher than the outlet at the lower end. This leaves 120 feet of pressure to be used, and as soon as the cold weather is over the water will be turned through again, and there is no doubt but that 2,000 inches will go to Dutch Hill. The pipe only burst three times, so far, and that can be accounted for by the fact that the pipe-makers ran out of iron after the storm set in, and were obliged to use some that had been discarded and laid away as unfit to work. Mr. Keddie has lately surveyed two claims for the Cariboo Hydraulic Mining Company, who will perfect their title by a patent. The two claims embrace about 200 acres, and it is thought to be the splendid ground. They are called the Clear Creek and the Mosquito Creek claims. They will get their water from Butt creek, and will have every facility for working the ground easily and rapidly. The North Fork section shows every indication of permanent prosperity.

Daniels & O'Brien, on Whaponee creek, are still driving away at their head-rock tunnel, in hopes of getting beyond the old workings.

McCarger & Co. have commenced operations again on Whaponee creek.

SHASTA COUNTY.

QUARTZ.—*Shasta Courier*: We are gratified to learn that J. P. W. Davis, formerly of Healdsburg, has not only succeeded in benefiting himself, but has been the means of developing a new feature in Western Shasta, in the way of gold-bearing quartz. A mill is to be put up, and Mr. Davis has bonded three mines owned in Trinity for \$50,000. Judging from what we have seen and heard, we think there is something pretty good in Bullychoop.

SIERRA COUNTY.

Mining Items.—*Mountain Messenger*, Jan. 30: We understand that the Bald Mountain Mining Company lost all their sluices from the small dump to the bridge, and boxes were taken out in spots all the way down the creek.

John Conrad, one of the owners of the Iowa mining claim at Mt. Pleasant Ranch, informs us that the bed of blue gravel which they have struck is six feet in thickness, and prospects well all through. The company have not yet decided how they will work their claim. It is said that a tunnel can be run in to tap the channel within 2,300 feet or less. Work will be suspended for a time.

We are informed that the high water in Slate Creek did a great deal of damage in Scales' Diggings. The high bridge on the creek at that place was carried away, and the flumes, etc., crossing the creek were badly wrecked. The two large reservoirs belonging to the Boyce Bros., were broken and ruined, and one he belonging to Col. Williams was also destroyed. On Sunday a slide occurred in Col. Williams' diggings, damaging a large quantity of pipe and doing other damage. Probably \$50,000 would not more than make good the damages done in this small camp.

SONOMA COUNTY.

CLOVERDALE MINE.—*Sonoma Democrat*, Jan. 30: The furnace of the Cloverdale mine is within a few days of commencing work. It would now be running but for the delay caused by the late storm in delivering some necessary articles. The furnace is well built, and stands upon the bank of Big Sulphur, about half a mile above the mouth of Squaw creek. Hones for men, shops, and other necessary sheds have been built, and all is ready for work. A railway is also completed from the mine to the furnace. The cars are raised and lowered by a wire rope. There is considerable ore on the dump, said to be of high grade. The Cloverdale will make a good showing among the mines in this county, which are now about ready for reducing ore.

The Livermore, under the charge of John Magoon, is progressing finely. The furnace there is also near completed. It will be ready for work as soon as the weather settles. The owners are sanguine and we wish them success. We are informed that R. S. Johnson, formerly of Mark West, and Dave Collier, have made a discovery of cinnabar on the Clear Lake and Cloverdale road.

MINES NEAR MERCURYVILLE.—*Cor. Russian River Flag* Jan. 28: At the Geyer mine, the furnace, (a Kuox & Osborn) was started on the first of January, and the first charge of ore was put in on the 3d inst. On the 6th the mercury flowed from the condensers—a remarkable occurrence, and unprecedented in the history even of this ex-flood furnace. The ore is delivered in carts from the mine above the furnace from 5 or 6 different places. This mine is destined to be a wonderful property. The Superintendent told me that the vein was 150 feet thick, with pay ore all throughout. On my return past the Oakland, found a boy lot of men assaying ore and shipping it to the Ida Clayton furnace, with the tunnels going ahead and shafts sinking, taking out rich ore to supply the furnace which is to be built on the mine in the spring. I found the Missouri retorts run-

ning on ten per cent ore from the Georgia, owned by Thompson Brothers, of Pine Flat and Reynolds of Healdsburg. The mines about this flourishing camp employ about 200 men now and will employ perhaps five times that number in the spring.

TRINITY COUNTY.

RUSHING THINGS.—*Trinity Journal*, Jan. 30: The Weaverly D. & H. M. Co. has been mining the Ware mine day and night up to Wednesday, when the supply of water getting short, they were compelled to discontinue night work. Six thousand feet of bed-rock has been stripped.

GOON PROSPECTS.—Later advices from Cinnabar confirm the news last week regarding the strike made by the Trinity company. Six feet of good cinnabar ore has been cut through by their tunnel. Stock in the company has an upward tendency.

Although miners throughout the county are doing some work, the supply is not sufficient to keep them steadily employed. Frost and wind during the past week has reduced the supply to a great extent.

TUOLUMNE COUNTY.

NEW ALBANY MINE.—*Tuolumne Independent*, Jan. 30: The recent development in the New Albany mine, in the opinion of those who have examined it thoroughly, will prove to be the most important strike, as regards size and richness, that has been made in this county for many years. The vein was tapped in a level running south from the shaft, some 50 feet below the level of the main tunnel, which disclosed a large body of ore, pitching with considerable inclination, and showing free gold in a dark blue sulphuretted hearing ore, pronounced by all who have seen it, to be of extraordinary richness. The shaft is being driven down below this level as rapidly as possible, and when they arrive at a depth of 60 feet a level will be run to strike the shaft, from whence they will proceed to extract and raise this valuable and seemingly inexhaustible body of ore. Dr. J. Walker, under whose faith and intelligent administration the work has been so successfully prosecuted, will leave for San Francisco in the course of a week or ten days, with the view of perfecting arrangements with his company, for a mill and hoisting works.

ANOTHER MARBLE STRIKE.—Hugh Coyle & Co. have taken up a marble lead at the upper edge of town, which promises to be of great value. It measures 200 feet wide and crosses a ten acre lot. The marble is pure white, clean and free from dirt, and the specimen we have before us we believe would make a white mark on the "beautiful snow." It will be excellent for statuary.

Nevada.

WASHOE DISTRICT.

CONSOLIDATED VIRGINIA.—*Gold Hill News* Jan. 28: Daily yield, 400 tons of ore. This ore is mostly extracted from the 1300 and 1400-ft levels although the running of cross-cuts and prospecting drifts necessitate the extraction of some ore from the 1500 and 1550-ft levels. The ore breasts both north and south on the 1300 and 1400-ft levels are yielding splendidly. The north drift on the 1500-ft level has penetrated the California ground a distance of 70 feet, the face still in the same immensely rich chamber of ore as that heretofore described. The bottom of the winze below the 1550-ft level is still in the richest possible character of ore. The 1500-ft level is opening up magnificently at all points, and the prospects of the main mine never were brighter than at the present. The new mill is working splendidly, crushing about 250 tons of ore per day. The old mills are all working up to their full working capacity, and good returns may be looked for.

OPHR.—The ore slopes between the 1300 and 1455-ft levels as well as those on the 1455-ft level are all looking well and yielding the usual amount of high grade ore. The bottom of the north winze on the 1455-ft level, still continues in the finest quality of rich ore. Assays from the bottom of the winze last evening gave over \$1,000 per ton as the result. The southeast cross-cut, on the 1455-ft level, is passing through a very favorable formation, cutting occasional streaks of low grade ore, a formation similar in almost every respect to that penetrated by the east cross-cut in the Consolidated Virginia mine before cutting their immense rich ore body. The repairs to the drift on the 1700-ft level are completed, and cross-cutting has commenced so that some good developments may be looked for in that quarter soon.

BELOHER.—The bottom of all three of the prospecting winzes below the 1400-ft level are in fine ore, and the prospects of the lower levels are apparently on the increase daily.

CALIFORNIA.—The face of the cross-cut on the 1500-ft level, near the south line, is still in the richest possible character of ore. The face of cross-cut No. 2, on the same level, is now penetrating the same character of material as that found in the cross-cuts further to the southward just before striking the rich ore found in the other cross-cuts and in Consolidated Virginia.

LADY BRYAN.—The prospecting drifts, both north and south at the first of the new shaft are showing fine ore, and great expectations are based upon developments about being made by a cross-cut started a short time since to cut the ledge further to the northeast than it has yet been prospected.

DAXTON.—The face of the south prospecting drift at the third station level is in a fine quality of red sulphuretted ore, which is rapidly proving itself a fine development.

CROWN POINT.—Sinking the main incline is making excellent progress. The incline is fast

approaching the 1700-ft level, at which point a new station will be opened and a drift started to prospect the ledge. The main east drift on the 1600-ft level is being pushed ahead toward the ore vein as fast as the nature of the work will permit. The ore breasts between the 1500 and 1400-ft levels continue to yield a good supply of good ore. The ore breasts on the 1300-ft level are also yielding a considerable quantity of good ore. Daily yield, 400 tons of ore.

KOSSUTH.—Sinking the south winze on the ore body found in the south drift at the first station level has been stopped by a flow of water for the present.

UTAH.—Preparations are being made for the erection of new and powerful pumping machinery for draining the water from the shaft and prospecting the mine to a much greater depth than it has yet been prospected.

WONVILLE.—The ore breasts at the 300-ft level of the old works are looking well and yielding the usual amount of good milling ore.

CHOLLAA-POTOSI.—The only work being done in the mine at present is the putting in of new and powerful pumping machinery at the 1100-ft station of the incline.

IMPERIAL-EMPINE.—The main east drift on the 2000-ft level is being steadily driven ahead, with increasing prospects of soon reaching the main ore vein.

HALE & NOACROSS.—Daily yield, 40 tons of ore, from the old workings south, at the 11th station level.

JULIA.—The main south drift on the 1000-ft level is being steadily driven ahead, following the west wall of the ledge, occasionally cutting some fine streaks and bunches of ore.

UNION CONSOLIDATED.—The face of the northeast drift on the 1300-ft level is still in very favorable ledge material, containing streaks and spots of fine looking quartz.

JUSTICE.—The connection is not yet completed between the mining drift north from the Waller Defeat section and that coming south from the 400-ft station of the Justice shaft, but it will be very shortly, after which good developments may be looked for in cross-cutting at that level.

GEOROLA.—A fine, first-class working shaft, of three compartments, has been commenced, the tunnel explorations having indicated the most advantageous point for sinking. Powerful machinery is engaged for the hoisting works, sufficient for working the mine to a depth of 1500 ft.

FLORIDA.—Main shaft down 377 ft to-day, with the bottom in very favorable ground with occasional stringers of quartz coming in.

BULLION.—The south drift on the 800-ft level is still showing some excellent prospects of good ore. The north drift on the 1700-ft level is steadily developing better indications of a paying ore vein.

AMERICAN FLAT.—The prospects for good ore developments on the 750-ft level are excellent.

JACOB LITTLE CONSOLIDATED.—The old Jacob Little, on Cedar Hill, having been consolidated with other valuable ground adjoining, is now about being worked up once more.

NEW YORK CONSOLIDATED.—The prospects of a fine ore development on the 700-ft level are excellent.

IOWA.—The prospects of soon cutting the ore vein are growing better every day.

NIAGARA.—Preparations for the erection of the new hoisting works are going steadily on without interruption. The ore prospects in the surface incline are improving.

PHIL SHERIDAN.—Main west drift in 243 ft. The ledge looks finely, and excellent assays are obtained, which improve as further advance is made.

MEXICAN.—The face of the north drift, on the 1455-ft level of the Ophir, is gradually improving as the work advances. Some fine looking quartz, giving excellent assays, has been encountered.

ANDES.—Development of ore bodies going ahead as usual, but milling facilities are lacking at present.

Montana.

BANNOCK MINES.—*Montanian*, Jan. 21: In this particular section we are highly favored in respect to lodes of superior quality. As an illustration of this fact we refer to the Delmonte, owned by Sears & Smith. Under the skillful management of Messrs. Peck and Bray, after a heavy expenditure of time and money, these energetic gentlemen have developed a mine of inestimable value, attracting the attention of capitalists from Utah, California, and all parts of our Territory. The ore is exceedingly rich in silver, as various assays and shipments have amply demonstrated, and as a natural consequence the value of this mine is rapidly increasing and a new impulse is being given to quartz mining here.

THE SMELTING WORKS.—The smelting works recently burned at Jefferson City are being rebuilt with all possible dispatch. Mr. Nowlan is helping to develop the camp by constructing roads to the adjacent mines, in order to obtain the quartz to furnish the works as soon as they are rebuilt. Con. Cannon, the popular hash vendor at the Merriman House, is a man of large calibre, and deserves a large share of public patronage.

PLACER DIGGINGS.—Extensive placer diggings have been found by Messrs. Kelly and Furvine, in the foothills of the Blue Wing district, near Bannock, but, owing principally to the scarcity of water, they will probably remain unworked for a time.

THE PIONEER QUICKSILVER MINE.—Known as the Socrates, in Sonoma county, was sold last week for \$200,000. The Flagauff, adjoining, was sold to the same purchasers for \$60,000.

The "Tailings" Question.

The Nevada Transcript says: The results of the last storm presents a question of serious import to the people of both the agricultural and mining sections of the State. There is no doubt but a large share of the lands adjoining the rivers which carry the water from the mountains to the ocean, have been flooded, and irreparable damage has been the result. It is evident that no system of damming can prevent an overflow when such a freshet as the last occurs. What are the owners of farms to do? It is evident mining can never be etopped. It is an industry the whole world desires to foster. The Government will encourage it, notwithstanding agriculture may suffer. Hydraulic mining is in its infancy. The very storms which are so destructive to the valleys are just what the mines require. The sediment, which has been accumulating for years in the ravines and river beds, and preventing a proper fall, has all been washed away, and made a place for the deposit of other quantities unwashed. There are thousands of acres of gravel unwashed to one which has been washed. Each year adds to the amount of sediment deposited in the valleys. Fifty years hence the whole surface of the country there will be raised much above its present level, by the accumulation of dirt washed down from above. Men have invested their money and labor there to make homes and develop the resources of the country and they find themselves each successive winter subject to an overflow which renders their property valueless. The same process will be continued as long as mines are worked in the mountains. We believe this state of facts exist only on the Sacramento, American and Feather rivers, above Sacramento. It is evident mining will have to be etopped or that country will have to be abandoned for its present purposes, unless some method can be devised to overcome the difficulty. It is certain mining will never be etopped. So the question as before stated, becomes one of serious import, and will continue to attract the serious consideration of the residents of both sections. What relief can be afforded we cannot apprehend. The question is a complicated one and full of difficulties.

Mining Claims in River Beds.

The Commissioner of the Land Office, in a letter to the Surveyor-General of Montana, wrote as follows:

"So far, however, as your letter may be regarded as asking the advice of this Office for your own guidance upon the subject-matter therein submitted, I have to say, generally, that the mere fact that the banks of a stream are meandered is not conclusive of its navigability. The question is one of fact, and the rule is thus stated:

"Rivers are deemed navigable waters of the United States when they are used, or are susceptible of being used in their ordinary condition, as highways for commerce between the States." (10 Wallace, 557; 11 Wallace, 411.)

The general status of the navigable waters of the United States is thus declared:

"The shores of navigable rivers and the soil under them were not granted by the Constitution to the United States, but were reserved to the States respectively, and new States have the same rights, sovereignty and jurisdiction over this subject as the original ones." (3 Howard, 212; 9 Howard, 471; 13 Howard, 25.)

For general discussion and determination of the rights of proprietors in lands bordering on navigable rivers, under the acts relating to conveyance and sale of public lands, see Railroad Company vs. Schurmeir. (7 Wallace, 272.)

This office will not in any way complicate the full jurisdictional rights in navigable rivers now in territorial limits, but which must in future fall within the boundaries of a new State, by an attempted sale of any portion of the beds of such streams.

The ninth section of the Act approved May 18th, 1796 (1 Stats, 468), furnishes a rule upon the subject of the proprietorship of the stream and the bed of non-navigable rivers.

The last clause of that section is in the following words, viz.: "That in all cases where the opposite banks of any stream not navigable shall belong to different persons, the stream and the bed thereof shall become common to both."

GEOLOGICAL SURVEY IN MASSACHUSETTS.—They are talking of another geological survey of Massachusetts. The last survey was in 1830, and was incomplete. The Committee on the subject say that there are extensive coal and lead measures not yet determined, and deposits of iron. It is probable that the survey will extend over a period of fifteen years and the estimated cost is \$25,000 per annum. We have heard it stated in this city that Professor Whitney, formerly chief of the State Geological Survey of California, is looking out for a similar appointment on the proposed Massachusetts survey. We do not know how much truth there is in the statement.

BASE BULLION.—The exact number of bullion bars shipped from Cerro Gordo by the Cerro Gordo freighting company, from January 1, 1874, to the first of the present month, was 123,176, averaging 82½ pounds each—5,050 tons.

The first shipment of quicksilver from Mendocino county was forwarded to San Francisco a short time ago from the Empire mine on Dry creek.

The Alfalfa Parasite:

Improved agriculture is of so recent a date in California, that but few of the pests in the way of insects and weeds that trouble the cultivator in the older States, have come to plague his California brother. Alfalfa or lucerne is one of the staples of California agriculture, and a weed that threatens the destruction of this crop, is a matter of the first importance. Notices of a particularly troublesome dodder have appeared in the California papers, and we are indebted to the kind attentions of our friends of the PACIFIC RURAL PRESS, of San Francisco, and of the Sonoma Democrat, for specimens, which have enabled us to examine the plant, and to make an engraving of it. Almost every one knows our common dodders, which hang their yellow or copper-colored, wiry stems over the bushes in the swamps of the Atlantic States. There are ten native species east of the Mississippi, several more west of that river, and about seventy species thus far known throughout the world, all of which, with their varieties, are admirably described in Dr. G. Engelmann's elaborate account of the genus. The dodders are all parasites; the seed germinates in the ground, and the stem attaches itself to some other plant; by means of numerous disks or suckers, it draws upon the plant for nutriment, and soon cuts itself loose from the root, and feeds wholly upon its unfortunate host. Some dodders live upon exogenous plants in-

should be taken to prevent its spread. Cut the infested plants, and burn them, and do this before the parasite has matured its seeds. If the dodder has too full possession to allow this to be done, then the plan followed in France, (where a dodder, and probably the same species, is destructive,) may be adopted. Straw is laid in abundance among the plants in a dry time, and then set on fire; the sudden flame destroys the parasite, but does not materially injure the alfalfa, which starts from the roots, and the stems, that escape injury by the fire.—American Agriculturist.

COAL LANDS.—The Commissioner of the Land Office has addressed a letter to the attorney of the Union Pacific Railroad Company, which is applicable to other railroad lands when the United States government made grants from the public domain. The letter is in answer to one written by the attorney requesting the Commissioner to continue the act of June 22, 1874, for the relief of settlers on railroad lands, so as to permit the Union Pacific railroad to select lands containing coal and iron, in lieu of agricultural lands, proposed to be released in favor of actual settlers. The Commissioner in reply reviews the several acts applying in the case, and concludes as follows: "Your company receives all its coal and iron lands without diminution on account of the claim of any settler. To allow you in addition to select lands purely agricultural, and take

A CALIFORNIA WEED—DODDER UPON ALFALFA.

discriminately, while others prefer particular plants, or those of certain families; one confines itself to flex, which, besides the one in question, is the most generally injurious. One of our native species has been known to be troublesome upon young trees in nurseries. The dodder upon alfalfa, so far as we can determine from description, having no authentic specimens for comparison, is *Cuscuta racemosa*, variety *Chiliana*. The species is a very variable one, and between it and related species there is some confusion. The seeds of this were no doubt introduced into California with alfalfa seeds from Chili, the same as it was into Europe many years ago, where it was very destructive to lucerne, often destroying whole fields. The engraving shows the habit of the weed; when once fixed, it spreads and entangles the several branches of a plant, or those of neighboring plants; under this heavy draught made upon its life-blood, as we may regard the sap, the lucerne ceases to grow, and at length turns yellow, and dies from exhaustion. The Sonoma Democrat publishes an opinion that the dodder now so troublesome upon the alfalfa is a native species, but an examination of the specimens makes us quite sure that it is not. One not acquainted with the minute characters, by which the species are distinguished, might, from their outward resemblance, regard them as the same. At the lower left hand of the engraving the relative size and shape of the two seeds are shown, both of course magnified. The alfalfa seed is like a minute, rather flattened, kidney bean; that of the dodder is irregularly orbicular, and only about one third as long as the other. An ordinary magnifier will readily detect the presence of this or other foul seeds in the alfalfa seed. With this, as with other weeds, one important point is to avoid introducing it, and care in selecting the seed will do this. Where it makes its appearance the most prompt measures

therefor reserved coal lands of greatly increased value, would in my opinion materially enlarge your grant, and would therefore be in express violation of the act under which the claim is presented."

SAN DIEGO MINES.—The patent has been issued for the Cuyamaca rancho, San Diego county, containing 35,000 acres. The confirmee is Augustin Olvera, former owner of the grant. The patent conforms to the decision of the Interior Department, excluding Julian and Banner mining districts from the survey. The receipt of the patent settles the long contested controversy between the grant owners and miners, and gives the latter a right to work unmolested. A letter to the San Diego World from Julian, dated January 18th, says that James Pascoe, who made the original survey of the Cuyamaca grant, which caused so much litigation and which has since been thrown out by the Interior Department, visited Julian last Monday, when the citizens hung and burnt him in effigy.

MANY valuable improvements have recently been made in the machinery of E. T. King & Co's paper mills, at Seratoga, and a new boiler has been put up with arrangements for consuming all the smoke. The company is now working a full force of hands, and the mill is turning out large quantities of paper.

THE strike in the Welch coal mines is still unsettled. In some of the mines men are at work. Violent disturbances are frequent in consequence of the workers being interfered with and intimidated by strikers.

PROCEEDINGS have been begun in the U. S. Circuit Court by Charles C. Coolidge against J. Hendy, to obtain \$180,000 and costs of suit, for an illegal infringement of a patent for concentrating metallic ores.

Placer Claims.

The following letter from S. S. Burdett, Commissioner of the General Land Office, to Congressman Page, is of importance. He says: The size of placer claims located prior to Act of July 9, 1870, is regulated and controlled by local law. Subsequent to July 10, 1870, and prior to May 10, 1872, no location of a placer claim can exceed one hundred and six acres.

From and after the passage of the mine act of May 10, 1872, no location made by individual can exceed twenty acres, and no location by an association can exceed one hundred and sixty acres.

There is nothing in the Mining Acts of Congress forbidding one person, or an association of persons, purchasing so many separate distinct locations as he or they may desire, embracing in one application for a patent entire claim to which they have the position and the right of possession by virtue of compliance with local laws and congressional enactments.

The law does not require an expenditure of \$500 upon each location of a placer claim, embraced in an application for patent where locations are contiguous and constitute one claim.

Where an application embraces two or more separate and distinct tracts of placer mining ground, the required amount, viz: \$500, may have been expended upon each tract, so copy of the notice and diagram posted up each tract to entitle the claimant to make a thereof.

FIRST SHIPMENT.—The Humboldt mill mining company, recently incorporated in San Francisco, made its first shipment of bullion last evening. It consists of three bars of bullion, the assayed value of which was \$2,000. The bullion was from ore from the company's mine in Winnemucca mountain, which is producing well, and has the advantage of being easily worked, the country rock adjoining vein being what miners term "picking ground." Joseph Ginacos is Superintendent of the company's mill and mine, and under his experienced management good results may reasonably be expected.—Silver State.

THE Sierra Nevada mine produced bullion the value of \$90,700 during the past fiscal year. The principal source of revenue, however, the pockets of stockholders, which panned \$250,000 on three assessments. The company are engaged in sinking a new shaft, and \$210,000 was spent last year on that account. There was also \$71,000 paid on account of hoisting ore and other work in the mine, \$49,500 on account of the Sacramento-Sierra Nevada mills. The financial condition of the company shows that there is still \$3,000 cash on hand, and \$2,200 due from assessments. There are no liabilities.

NEW DISTRICT.—At a miners' meeting at Lang's station, Los Angeles county, on 12th inst., a new mining district was formed called the "Blue Ledge District." It is north of San Fernando mining district, connecting on the same, and extending north to the summit of what is known as Chico Mountains.

HOWLAND tunnel in the Little Cottonwood district, Utah, will be about 6,000 feet in length when completed. It is to penetrate the mountain belt from the base of Emma Hill, and the general course is northeast. The tunnel will be through the Flagstaff, Vallejo, Ohio, San Hiawatha, Emma, Diamond, Davenport and other mines.

THE Salt Lake and Ogden Railroad Company, lately incorporated, is to build a narrow-gauge railroad from Ogden to Salt Lake, making a continuous line of narrow-gauge between different mines of the Territory and Idaho. Active operations have already been commenced.

BRANCH MINT.—A bill has been introduced in Congress providing for the establishment of a branch mint at Omaha, with the fitting office superintendent, assayer, melter and refiner and the requisite clerks. An appropriation of \$150,000 is asked to meet the expense of the building and machinery required.

A rich deposit of quartz has been struck 10 feet down from the top in the old Greer claim, two and a half miles north of Vallejo, which pays from \$60 to \$65 per ton, and the ore is getting better as they go down. The casings pay from \$25 to \$30 per ton. The vein is from 15 to 18 inches in width.

THE San Juan Times of Saturday says that a land slide at Forest City, Sierra county, buried a house away, and one bridge there was swept off. The Beld mountain company, 1,000 feet of flume and all the gold therein obtained. As the gravel of that company is exceedingly rich, the loss is heavy.

THE force at the Globe foundry, Stockton, on the iron work of the two stern wheel steamers ordered some time ago for a Rensselaer company, to ply on the Amoor river. The boats will cost \$16,000 each, and will be ready for shipment in about a month.

THE people in Truckee are elated over discovery of the bonanza, on account of the land which it will create for their lumber, most of which will have to come from the mills.

GOOD HEALTH.

The Philosophy and Relative Warmth of Clothing.

A London medical journal says that Dr. Von Stenckner, in a careful study of this subject recently published, has pointed out that the permeability of stuffs to air is a condition of their warmth. Of equal surfaces of the following materials, he found that they were permeated by the following relative quantities of air, the most porous flannel, such as is used ordinarily for clothing, being taken at 100: Flannel, 10; linen, of medium fineness, 58; silk, 40; tick-kin, 58; tanned leather, 51. Hence, if the warmth of clothing depend upon the degree in which it keeps out the air from our bodies, then a glove must be 100 times warmer than flannel, which every one knows is not the case. The whole question, then, is resolved to that of ventilation. If several layers of the same material be placed together, and the air be allowed to penetrate through them, the ventilation through the second layer is not much less than through the first, since the meshes of the two form a system of continuous tubes of uniform diameter, and the rapidity of the movement of the air through those, is affected merely by the resulting friction.

Through our clothing, then, there passes a stream of air, the amount of which, as in ventilation, depends upon the size of the meshes, upon the difference of temperature between the external and internal atmosphere and upon the locality of the surrounding atmosphere. Our clothing, then, is required, not to prevent the admission of the air, but to regulate the same so that our nervous system shall be enabled to have no movement in the air. Farther, our clothes at the same time, regulate the temperature of the contained air as it passes through them, so that the temperature of the air between the clothing and the surface of our body averages 84 to 86 degrees Fahrenheit. The hygroscopic property of different material used for clothing essentially modifies their actions. This property varies with the different materials; wool, for instance, takes up more water than linen, while the latter takes up and gives off its watery contents more rapidly than the former. The more the air is displaced by water from the clothes, the less will be their power of retaining the heat; in other words, they conduct the heat more readily and hence we are quickly chilled by wet garments.

About One's Self.

The object of brushing the teeth is to remove the destructive particles of food which by their decomposition generate decay. To neutralize the acid resulting from this chemical change is the object of dentifrice. A stiff brush should be used after every meal, and a thread of silk or India rubber passed through between the teeth to remove particles of food. Rinsing the mouth in lime water neutralizes the acid.

Living and sleeping in a room in which the sun never enters is a slow form of suicide. A sun bath is the most refreshing and life-giving bath that can possibly be taken.

Always keep the feet warm, and thus avoid colds. To this end, never sit in damp shoes or wear foot coverings fitting and pressing closely. The best time to eat fruit is half an hour before breakfast.

A full bath should not be taken less than three hours after a meal. Never drink cold water before bathing. Do not take a cold bath when tired.

Keep a box of powdered starch on the washstand; and after washing, rub a pinch over the hands. It will prevent chapping.

If feeling cold before going to bed, exercise; do not roast over a fire.

THE VIRTUES OF BUTTER MILK.—Mr. Robing, in a paper presented to the French academy, has extolled the virtue of buttermilk: Life exists only in combustion, but the combustion which occurs in our bodies, like that which takes place in our chimneys, leaves a detritus which is fatal to life. To remove this he would administer lactic acid with ordinary food. This acid is known to possess the power of removing or destroying the incrustations which form on the arteries, cartilages and valves of the heart. As buttermilk abounds in this acid, and is, moreover, an agreeable kind of food, its habitual use, it is urged, will free the system from these canases, which inevitably cause death between the seventy-fifth and hundredth year.

HOUSE WINDOWS.—The more light admitted to apartments the better for those who occupy them. Light is as necessary to sound health as it is to vegetable life. Exclude it from plants and the consequences are disastrous. They cannot be perfected without its vivifying influence. It is a fearful mistake to curtain and blind windows so closely for fear of injuring the furniture by exposure to the sun's rays; such rooms positively gather elements in darkness which engender disease. Let in the light often and fresh air too, or suffer the penalty of aches and pains and long doctor's bills, which might have been avoided.

TO PREVENT BALDNESS, says a correspondent, throw away all oils and pomades, and wash the parting of the hair with cold water, night and morning, dry thoroughly, and then use a good stiff brush, and keep brushing until redness or a warm glow is produced.

The Abuse of Appetite.

The appetite is one of the least appreciated of nature's gifts to man. It is generally regarded in this work-a-day world as something to be either starved or stuffed—to be got rid of at all events with the least inconvenience possible. There are people who are not only glad that they have been endowed with sound, healthy bodies, for which nature demands refreshment and replenishment, but they are actually ashamed to have it known that they are sustained in the usual manner. The reason of this we are at a loss to conceive. Everybody admires beauty, and there can be no true beauty without good health; and no good health without a regular and unvarying appetite. We are disinclined to let appetite take any responsibility on itself. If we happen to consider it too delicate, we try to coax it, perhaps stimulate it with highly seasoned or fancifully-prepared food. There are times when this may seem necessary, as in the case of a person so debilitated as to depend for daily strength on what he eats. But, usually, the cajoling process is a mistake. If the appetite of an individual in fair bodily condition be occasionally slender, it is no cause for alarm, and it should be allowed to regulate itself. It may safely be considered nature's protest against some transgression, and it is wise not to attempt coercion.

At certain seasons, as in spring and summer, the appetite of even the robust is apt to fail, and the relish for meats and heavy food to wane. This is all right enough, for animal diet in warm weather heats the blood, tends to headaches, and is generally unwholesome, unless sparingly used. On the other hand, fresh vegetables, berries, fruit and bread are cooling, corrective, and what the palate most craves. Don't be afraid to go without meat a month or so; and if you like, live purely on a vegetable regimen. We will warrant that you will lose no more strength than is common to the time, and that you will not suffer from protracted heat, as when dining on the regulation toast. —Good Health.

HEART DISEASE AND SUDDEN DEATH.—Do not all persons with heart disease die suddenly? By no means. The popular impression is that all heart diseases entail a probability of sudden death. Dr. Lancereux states that the ordinary termination is slow death, due to the increased difficulty in the circulation, and to the organic lesions that this induces. A less frequent termination he calls rapid death. This is caused by some sudden impediment, more or less complete, to the introcardial circulation, such as a displacement of fibrinous concretions in the heart, or rupture of the valves. In this case death ensues in from ten to fifteen minutes. A third mode of ending is sudden death, which, of course, frequently happens under certain circumstances.—Herald of Health.

GREEN TAPERS POISONOUS.—The use of red and green wax tapers on Christmas trees is pronounced highly dangerous by the *Popular Science* monthly on account of the poisonous nature of the colored matter employed. Yellow and blue tapers are harmless.

USEFUL INFORMATION.

THE improved German bleaching process, known as Pabst's, is spoken of in foreign journals as an important success. It consists in first dissolving about nine pounds of permanganate of potash or soda, in water, and then adding one-fourth this quantity of sulphate of magnesia dissolved in water. The color of the liquid is then a very fine violet, and the amount thus prepared will suffice for about two hundred and twenty pounds of wool. A sulphurous acid bath is also prepared, heated to seventy-seven degrees, Fahrenheit, when used. The materials to be bleached are first thoroughly cleansed, and then kept in the permanganate bath for a quarter of an hour, on withdrawal from which they are found covered with a deposit of peroxide of manganese. They are next introduced into the sulphurous acid bath, which reduces the peroxide of manganese to the peroxide, the salts of which are readily removed by subsequent washing. If the yarns or fabric resist the bleaching process, they are treated with hydrochloric acid, containing one part of commercial acid to twenty parts of water. One special advantage of this process is, that it affords a means by which even indigo may be discharged by a series of successive bleachings, leaving the stuff fit for re-dyeing.

SOMETHING NEW IN THE PRESERVATION OF FRUIT.—The following method for the preservation of fruit has been patented in England. The fruit is placed in a vertical vessel in layers, separated by layers of pulverized white sugar, and is then covered with alcohol of 80° Gay Lussac. After twelve hours the closed vessel is inverted and the maceration allowed to continue from 12 to 72 hours, according to the nature of the fruit, which is then removed and allowed to drain and dry. About two pounds of sugar and two pounds of alcohol are recommended for four pounds of fruit.

NUMBER OF AMERICAN NEWSPAPERS.—There are now published in the United States and Canada 7,769 newspapers—of which number 7,360 are published in the States, and 409 in the Dominion of Canada. There are 400 papers printed in New York city.

THE ANTIQUITY OF IRON.—We are relieved from any doubt as to whether iron was in use 3,400 years ago by the discovery of a wedge or plate of iron imbedded in the masonry of the Great Pyramid itself. This instructive relic, like the half found magnifying lens found at Pompeii, throws much light on questions of early workmanship. It has been a great puzzle to those who attributed the first use of iron to a date not much more than 2,900 years back, how such sharp and well defined hieroglyphics could have been cut by the ancient Egyptians on porphyry, granite and the hardest stone. From the certain proof that iron had been produced and wrought in the age of King Cheops, 5,400 years ago, we can better understand how the innumerable and exquisitely sunk symbols and figures were wrought on tombs, temples and sarcophagi. And more than that, from the great similarity in the mode of treatment that prevailed from the time of the Ptolemies back to the very earliest known Egyptian inscriptions, we have sometimes closely approaching a proof of the use of iron as far back as the fifth Egyptian dynasty, if not in the time of Moses himself; that is to say, six thousand three hundred years ago.

PREVENTING THE DECAY OF SHINGLES.—A CHEAP WAY.—Take a large kettle or tub that will hold about a barrel and fill it half full of wood ashes or potash lye, add to the liquid about three pounds of alum, and as much salt as will dissolve in the mixture. Make the liquor quite warm, and put as many shingles in it as can be conveniently wetted at once. Stir them up thoroughly, and when well soaked take them out and put in more, renewing the liquor as necessary. Then lay the shingles, when dry, in the usual manner.

After they are laid, take the liquor that is left, put lime enough into it to make white-wash, and if any coloring is desirable add ochre, Spanish brown, lamp-black, etc., and apply in the roof with a brush or an old broom. This wash may be removed from time to time. Salt and lye are excellent preservatives of wood. It is well known that leach tubs, troughs and other articles used in the manufacture of potash never rot. The become saturated with alkali, turn yellowish inside and remain impervious to the weather.

WEIGHT BY MEASURE.—It will be a very great convenience in the family, and sometimes elsewhere, to remember the following:

Wheat flour, one quart is one pound.
Indian meal, one quart is a pound and two ounces.

Batter, when soft, one quart is one pound and one ounce.

Loaf sugar, broken, one quart is one pound.
White sugar, powdered, one quart is one pound and one ounce.

Best brown sugar, one quart is one pound and two ounces.

Eggs, average size, ten eggs are one pound.
Sixteen large table-spoonfuls are a half pint, eight are a gill, four are a half gill, etc.

DON'T SELL THE PELTS.—The skin of an animal, whether cow, calf, colt or horse, that dies on the farm is worth more at home than at the tanner's. Cut it into narrow stripes, and shave off the hair with a sharp knife before the kitchen fire, or in your workshop on stormy days and evenings. You may make them soft by rubbing. A rawhide halter strap an inch wide will hold a horse better and last longer than an inch rope. It is stronger than hoop-iron and more durable, and may be used to hoop dry casks and boxes, and for hinges. Try it on a broken thill or any woodwork that has been split. Put it on wet and nail fast. Thin skins make the best to use it in its natural state. For other purposes it may be dressed.

HOW TO PREVENT DAMP FROM ENTERING INTO STONE.—The following ingredients melted and mixed together and applied while in a hot state to the surface of the stone, will prevent all damp from entering into it, and also those vegetable substances from growing upon it: 1½ pounds of rosin, 1 pound of Russian tallow, 1 quart of linseed oil. This simple remedy has been proved upon a piece of very porous stone made into the form of a basin, and two coats of this liquid being applied, caused it to hold water as any earthenware vessel.

FIRST USE OF ANTHRACITE.—It appears by letters embraced in the Penna manuscripts that anthracite coal was found in the Wyoming region, and a specimen sent to England in 1766. Heretofore it has been supposed that the discovery was first made about 1770 or 1771. In 1769, Thomas Penn, writing from London, refers to coal hills near Pittsburgh. A map of Pennsylvania, published in 1770, notes the existence of coal in the vicinity of Pottsville.

HEAT IN THE HUMAN BODY.—If the heat which a human body gives off in twenty-four hours could, consistently with life, be retained within the body, its temperature would, at the end of that time, have reached 185 degs., Fahrenheit, a temperature above the point of coagulation of albumen, and high enough to cook the tissues.

OREGON PINE.—A recent test of the relative strength of oak and Oregon pine made at San Francisco, with bars an inch square and three feet long, showed that the pine was equal to the oak. Both broke under the same weight placed in the middle of each bar, namely, 260 lbs.

DOMESTIC ECONOMY.

Flavorings.

Good flavorings are a most desirable addition over the cooking of olden times, when spices were the chief resort. These, however, are somewhat expensive, and thus many are deterred from using them in the common cooking of oakes, custards, puddings, etc.

But much can be done to help the matter by making some, at least, of our own "extracts." Vanilla beans are not expensive, and these boiled in milk flavor dishes nicely, and, we think, that the beans put into spirits would give a good extract at little cost.

Lemon, which is a more general favorite, can be easily made, and, when lemons are cheap, at a very small expense. Take the peel off, say of three or four lemons, and bruise or chop fine, and put it into a pint bottle, filling the bottle with good spirits, and, in a few days you will have a strong "extract," and at a cost of one quarter of what the small bottles of the same amount, would cost. To do this economically, the right season of the year, when lemons are low-priced must be chosen, and then enough can be made to last the year.

The oil of bitter almonds is also inexpensive, but great care must be taken in using this, as it is a violent poison, and needs but a mere trifle to flavor a pudding, custard, or other sauce, for which it is desirable. It is well to reduce a little of the oil, as for an essence, before using.

To those fond of flavorings, these hints may be acceptable and lead others to experiments of their own.

Beecher on Apples.

Rev. Henry Ward Beecher expatiates with true ecclesiastical unction on the manifold uses of the apple in the domain of culinary art. It might take its place on the table as regularly as the potato or the onion, for though "the onion is far more odorous, the apple is far more blessed." It is an admirable sauce for meat, which always craves a piquant acid for relish. When meat is wanting, "a scrap of pork in the frying pan, with sliced apples, will serve the economic table almost as well as if it had been carved from a beef or cut from a sheep." Mr. Beecher blesses the memory of the unknown inventor of the apple pie. He would fain make a pilgrimage to his grave and rear over it an everlasting monument. But the juice of the apple, he accepts only with discreet reservations. Though banished from its former universal position upon the farmer's table, cider is creeping back again, but it comes in the name of a neighbor, and is called champagne. Whether in one form or another, it is still savory of the orchard; it still brings warmth to chilly veins, and adds to the cheer of many a homely domestic festival. "I cannot," says Mr. Beecher, "as a temperance man, exhort you to make it, but I must say, that if you make it, you had better make it good."

PLAIN DIET.—This is what children ought on every account to be accustomed to from the first; it is vastly more for their present health and comfort than little nice things with which fond parents are so often apt to vitiate their appetites and it will save them a great deal of mortification in after life. If you make it a point to give them the best of everything; to pamper them with rich cakes, sweetmeats and sugar plums; if you allow them to say with a scowl, "I don't like this or that," "I can't eat that," and then go away and make them a little toast, or kill a chicken for their dainty palates depend upon it you are doing a great injury, not only on the score of denying a full muscle and rosy cheek, but of forming one of the most inconvenient habits that they can carry along with them in after life. When they come to leave you they will not half the time find anything they can eat—and thus you will prepare them to go chafing and grumbling through life, the veriest slaves almost in the world. Mothers, listen and be warned in time, for the time will come when you will repent; seeing your sons and daughters make their homes miserable by complaint, and raising their children up in the same way.—Rural New Yorker.

ABOUT BRAN.—Wheat bran is very much richer in phosphoric acid than corn bran. Wheat contains in the whole grain 8.2 per cent.; but nearly the whole of the phosphoric acid of the grain exists in the husk or bran. The wheat bran contains nearly twenty-nine per cent. of this valuable substance. What percentage is in the bran of corn we have no means of ascertaining, but it is certainly less rich in phosphoric acid than wheat bran.

Rye bran is richer still than wheat bran, containing over thirty-four per cent. of phosphoric acid, which is a larger proportion than is contained in any other article of food for poultry than the latter. If wheat bran is preferred free from damp or mould it will not deteriorate in quality or keeping for any moderate length of time, a year for instance.—New York Tribune.

STRENGTHENING JELLY.—Boil in two quarts of water one ounce of rice, one ounce of sage, and one ounce of barley, until reduced one-half. Strain into a mold; take a teaspoonful morning, noon and night. It can be sweetened and flavored to taste.

TABLE OF CONTENTS.

EDITORIALS AND GENERAL NEWS.

The Protracting Sextant—A New Instrument for
Hydrographic Work, 81. Among the Foundries and
Machine Shops; Academy of Sciences; Economic
Botany, 82-83. The Kilauea Fall, 89. Clearing Land
by Blasting; Hydraulic Mining in California; Industrial
Items; Patents and Inventions; Sensible; Locked
Out; Singular Discovery, and other Items of News,
92.

ILLUSTRATIONS.—Lowry's Protracting Sextant,
81. A California Weed—Dodder upon Alfalfa, 86.
Economic Botany, 82-83.

CORRESPONDENCE.—Chrome Ore in Napa
County; Colusa County Quicksilver Mines; The
California Blue Lead in Oregon and Washington
Territory, 82.

MECHANICAL PROGRESS.—Foundry Econ-
omy; English Railroad Iron; Superior Steel; Metal-
lic Contractions; Improved Turners for Forges; The
First Planing Machine; Large Hammer and Crane;
File-Cutting Machinery; Throwing Water from Pipes,
83.

SCIENTIFIC PROGRESS.—Science and Faith;
Tides of Lakes and Lakelets; Fall in the Value of
Amethysts; Use of the Spectroscope in Puddling;
Sewage Utilization; Rural Knowledge; Important
Discovery in Lubrication, 83.

MINING STOCK MARKET.—Thursday's Sales
at the San Francisco Stock Board; Notices of Assess-
ments; Meetings and Dividends; Review of Stock
Market for the Week, 84.

MINING SUMMARY from various counties in
California and Nevada, 85.

USEFUL INFORMATION.—Something New in
the Preservation of Fruit; Number of American
Newspapers; The Antiquity of Iron; Preventing the
Decay of Shingles—A Cheap Way; Weight by Measure;
Don't Sell the Pelts; How to Prevent Damp from
Entering into Stone; First Use of Anthracite; Heat in
the Human Body; Oregon Pine, 87.

GOOD HEALTH.—The Philosophy and Relative
Warmth of Clothing; About One's Self; The Virtues
of Buttermilk; House Windows; To Prevent Bal-
dness; The Abuse of Appetite; Heart Disease and Sudden
Death; Green Tapeworm Poisonous, 87.

DOMESTIC ECONOMY.—Flavorings; Beecher
on Apples; Plain Diet; About Bran; Strengthening
Jelly, 87.

MISCELLANEOUS.—Struck Pay; Webb's Flang-
ers; Something New; Cinnabar in Trinity; Blue Tent,
82. The "Tailings" Question; Mining Claims in
River Beds; Geological Survey in Massachusetts;
Base Bullion; The Alfalfa Parasite; Coal Lands; San
Diego Mines; Placer Claims; First Shipment; New
District; Branch Mint, 86. The Text Book Matter,
90.

THE PARTIES interested in the mining district
of Mud Lake are taking the proper course to
determine the value of their discoveries. A
three stamp prospect mill, to be run by an
eight-foot breast-wheel, is being framed in Reno
and will be shipped and set up in the district
as soon as completed.

THE Carson Mint has lately received a large
quantity of new machinery, including a grind-
ing machine, lathe machine, shaping machine,
hydraulic press, hydraulic pump, rolling ma-
chine, draw-bench, cutting press and coining
machine.

THE BOARD of Management of the Ruby Hill
Miner's Union has passed a resolution giving a
free use of its hall on Sundays for religious ser-
vices, without distinction as to denomination.

SENATOR John P. Jones and E. R. Burke have
purchased the remaining two-twelfths of the
Sumner gold mine, in Kern County, for \$150,-
000, which gives them the entire ownership.

PRATT's bill compelling miners to take out
patents for claims, whether they want to or
not, has been indefinitely postponed in Con-
gress, which action kills it.

THE company which recently purchased the
Pioneer claims, Sierra county, have already re-
ceived a portion of their freight and will at
once commence getting ready to open them.

ORE FOR LIVERPOOL.—The steamer "Dakota"
for Panama on the 23d inst., took on at Wil-
mington 738 sacks of Panamint ore, weighing
81,810 pounds.

THE mint fever is spreading. Chicago, St.
Louis, Cincinnati and Omaha want one. The
rest of the country is to hear from.

THE Nebraska mine, near Nevada City,
has struck a deposit of gravel yielding 12 ounces
to the pan.

THE Enreka Sentinel says there are over 1,000
tons of bullion in bars, now cooed up at the
Richmond smelting works, awaiting shipment.

Among the Foundries and Machine Shops.

The share-holders of the Lineeed Oil Mills
are so well satisfied with the profits of this con-
cern that they are about doubling the mechan-
ical capacity of the present apparatus for ex-
tracting the oil from the seed; and Messrs.
Booth & Co. are now engaged on designs for
another pair of oil presses with the hydraulic
pumps and connections for working the same.
The designs are in their hands, and we trust
they will carry this job through in spite of the
Eastern competition in price which they have
had to contend with in estimating, and prove
that in the now rapidly increasing demand here
for hydraulic machinery of this class, our re-
sources on the spot are sufficient to supply our
mechanical needs.

The Risdon Works.

The handsome little steamer built at these
works for the use of the Custom House
Officials in the harbor, was launched at these
works. The details of the machinery through-
out are unique. The hull, machinery and all
was built at the works, the Dickie Brothers
superintending the construction of the wood
work. The hull is of the following dimensions:
length over all, 68 feet; beam, 11 feet 6 inches;
depth of hold, 6 feet 6 inches. The timbers
are all of white oak, and the planking is of
cedar. All the deck fittings and facings are of
East India teak, and the bit-heads, mooring-
pipes and rudder, with all its fittings, are of
brass. The engine is of the surface condensing
type. The boiler is cylindrical, with one fur-
nace-flue, three feet in diameter, the diameter
of the boiler being six feet nine inches. The
boiler has 600 feet of heating surface, and will
be able to develop about 70 horse-power. The
propeller is 5 feet 10 inches in diameter and 9
feet pitch, and is made of hoes.

The Corliss valve, by which means the steam
is made to travel the least distance possible
from the steam chest to the cylinder, is gaining
in favor, and we notice the same applied to the
large hoisting engines now building at the
Risdon Iron Works. We think, however, that
the equilibrium stamp or lifting valve with
which most of the engines for mining purposes
built and building at the works have been
supplied, are on the whole preferable. The adjust-
ment being more simple, the liability to dis-
arrangement less; the greater durability giving
by far the least amount of friction surface and
the decrease in prime cost. Mr. Moore, the
able superintendent is now busily arranging
the plan for the steam hoists. The most im-
portant mechanical work connected with the
new Palace Hotel. We expect at an early day
to furnish our readers with details of this work,
the principle involved in the design being of
special interest.

Lifting Pumps.

At the machine shop of Messrs. Hendy, we
noticed a new design for a lifting pump, to be
worked by steam power, which is certainly
worth the consideration of all interested in
mines and other concerns when the question of
pumping on a large scale has to be considered.
The design, which is not limited to capacity,
was drawn out for an 8-inch ram, having a 5-
foot stroke. The outside of the ram clears the
pump barrel by $\frac{1}{4}$ of an inch, and works air-
tight in the necks or bodies of two stuffing
boxes fitted in the center of the pump barrel;
an ordinary lid and box is attached to either
end of the barrel for access to the check valves.
The bottom valve seat is fitted into the bottom
of the barrel. The top valve seat is cast solid
on the top of the ram. The facility of access
to the working parts, diminished friction and
convenience of this arrangement for mining
purposes is self apparent.

The Aetna.

The company incorporated a short time since
for the manufacture of linen, claims in the list
of its directors, Mr. Hanscom, of the Aetna
Iron Works. We understand that the plant, as
far as possible, is to be manufactured in this
city. That, as every one acquainted with this
class of manufacture is aware, includes a num-
ber of powerful presses driven by steam power
and worked by water pressure. This points
to busy times at the Aetna Iron Works at no
distant day.

Brass Fitting and Finishing.

One important branch of the machine and
steam engine trade has been gradually estab-
lishing itself in the midst of our foundries.
We allude to the brass fittings and finishing of
engines and boilers. First among the estab-
lishment of works competing in this class of
work is the firm of Garratt & Co. The compe-
tition of the agents of Eastern firms has been
somewhat severe in this department, these
goods being of easy transport. However,
scarcely a new piece of machinery is made
amongst us the finished fitting of which does
not bear the name of this firm and others sta-
tioned here. We noticed here a very elegant
little design of gearing being made. It consists
of a pendulum about five feet long, with rods,
stand, levers, shaft, etc., all of polished brass,
and was designed by Mr. Hedburn for connect-
ing with and working the indicator on the hori-
zontal engine in the new mint, which drives
the machinery when the load does not require
the power of the beam engine, of which men-
tion was made a short time since.

Hawkins & Cantrell

Have, in the course of some three years, built

up a nice little business in the specialty of
hoisting engines, and during the last few
months have been pushing a brisk trade in this
specialty, the material for the top stories of the
Palace Hotel and much of the shipping freight
being hoisted by engines made by them. One
of the first jobs they performed was to build
the handsome little beam engine that drives
their shop at the present time. They have just
had full sized designs prepared of all the work-
ing parts of their pattern of hoisting engines,
together with cloth tracings of the plans for
use in the work-shop, to facilitate the prepara-
tion of the different parts.

One department of mechanical engineering
offers at the present time a favorable opportu-
nity for the investment of skill and enterprise.
We allude to the small, strong and compact

Marine Engines.

Available for use in the numerous tugs which
find such remunerative employment in our
harbor. There is no reason why the engines
and boilers of the new tug just finished build-
ing between the ware-houses and dry dock
should not have been made here, taking into
consideration the freight and numerous extra
expenses in fixing and preparing for working
order this class of machinery brought from the
East.

We made an inspection of the engines of the
tug "Redmond" during two or three trips. The
engines, as far as coal consuming goes, will
compare favorably with any for similar pur-
poses. The design and details of the same are
scarcely uniform in any of the working parts,
crank shaft, rods, valve, gear, etc., having
been renewed from time to time with whatever
material was most handy for use. In this re-
spect the engines of the tug "Wizd" form a
marked contrast, the design throughout being
in uniform proportion. The link movement be-
ing specially good in this respect.

The Union Iron Works are to be moved with-
in a few months, over on the Potrero, where
extensive works are to be erected.

Academy of Sciences.

The regular meeting of the California Acad-
emy of Sciences was held on Monday evening,
Dr. Henry Gibbons, Second Vice-President, in
the chair. The following named gentlemen
were halloted for, and duly elected resident
members of the Academy: J. R. Scowden, Jere-
miah Clark, Horatio Stone, and Cornelius
Herz, M. D.

Donations to the Museum.

The additions made to the museum embrace
a number of interesting articles, the most val-
uable of which was received from J. C. Merrill
& Co., being a marine glass that originally be-
longed to Captain William Bligh, commander
of the British war-ship *Bounty*, which was
taken by mutineers in the last century. The
glass is of the old style, the case being about
thirty-six inches in length and covered with
leather, which has an antique hue, although
well preserved. It draws out in two sections
about eighteen inches longer, and is a glass of
good power. On the leather has been painted
the following inscription: "This glass origi-
nally belonged to Captain William Bligh, who
commanded H. B. M. ship *Bounty*, when taken
by the mutineers, who afterward settled on
Pitcairn's Island. It was left at Tahiti, and
from thence came into the possession of Kame-
hameha III., of the Hawaiian Islands, and was
presented by Kamehameha V. to Captain James
Smith, who left it with J. C. Merrill & Co.,
who presented it to the California Academy of
Sciences."

J. C. Raymond presented a valuable case and
drawers, also a collection of books for the
library.

J. C. Merrill presented a miniature Esquimaux
boot, a fine specimen of workmanship, and
whale's teeth.

Dr. H. Behr presented the web of the larva
of the *eucheira socialis*, a species of caterpillar,
from New Mexico, in about the same climate as
that of California. It feeds on a species of
arbutus, and could be introduced into this State
if desired. It forms a water-proof sack, into
which it retires for shelter from the weather.
The bag is remarkable for its exceeding delicacy
and lightness.

W. G. W. Harford presented several species
of crustaceans, from Santa Barbara.

Wm. J. Fisher presented thirty specimens of
crustaceans from Japan, Behring Straits and the
Arctic Ocean, several of which were new to
science, and none were before included in the
collections of the Academy.

Communications.

Mr. T. J. Lowry, of the U. S. Coast Survey,
read a paper on the "Protracting Sextant,"
which is given in another column.

Dr. Henry Gibbons read a paper on climatic
changes in California, which we will give next
week.

W. N. Lockington read an interesting and
exhaustive paper on sponges, illustrating his
remarks with diagrams.

Two papers were received from Dr. J. G.
Cooper, one "On Origin of California Land
Shells," and another "On Shells of the West
Slope of North America."

A paper was read from Professor George
Davidson, of the U. S. Coast Survey, President
of the Acad-my, giving a brief description of
the recent Transit of Venus, as observed by
him while in charge of one of the Government
expeditions for that purpose in Japan.

Economic Botany.

Second Lecture Delivered before the University of
Cal. College of Agriculture on Tuesday, Jan.
19, by Prof. C. E. Bessey, M. S., of the Iowa
College, Ames, Iowa.

[Reported expressly for the Press.]

Fungi Continued.

At the conclusion of the preceding lecture I
was telling you about these three forms, *Eci-
dium*, *Uredo* and *Puccinia*. You will recollect
that the *Ecidium* is the cup-like growth,
which after a while develops into something
which is quite different. De Bary thinks that
the spores of *Ecidium Berberidis* will not grow
upon the Barberry. They grow upon wheat
and produce first, *Uredo* and then *Puccinia*.
Uredo appears earliest in the season and has
rounded spores which are orange colored.
Later in the season there appear upon the
leaves of the wheat elongated black patches;
which, upon microscopic examination, are
shown to be composed of elongated spores. In
the first form, it has received the name *Uredo
rubigo-vera*; while in the second form it is called
Puccinia graminis. This last form is the true
rust. This theory is pretty generally accepted.
However, the two forms have been watched
carefully and found to run one into the other.

You will find that always in describing the
Puccinia, the kind of fruits are described; that
is, the elongated red spores. These, you un-
derstand, push through the epidermis, the leaf.
Now, these two, *Uredo* and *Puccinia*, are cer-
tainly the same, and the probability is that
Ecidium is but one of the forms of this poly-
morphic species.

Now, Botanists have not determined whether
the spores of *Puccinia* will germinate upon the
grass or not; or, whether it is necessary that
these pass back, and germinate again upon
the Barberry. The latter is probably the case.
The present state of our knowledge then,
amounts to this, that *Ecidium*, which grows
upon the Barberry is but one form of the same
plant which grows upon wheat; first as *Uredo*
and then as *Puccinia*. *Ustilago segetum*, (or
Ustilago carbo of some authors), is the next
one and belongs to this same group, No. IV,
and is the

Black Smut, Blast, or Blight.

Here is shown (Fig. 2,) a head of wheat, nat-
ural size, blasted, and also some of the spores
highly magnified. The spores are, as you see,
not entirely round, but somewhat flattened.

The next, *Ustilago Maydis*, is the one that
produces the black blast, or smut, on Indian
corn. (See fig. 3). Its spores, under the mi-
croscope, are found to be rounded, larger, and
are full of little prickles all over the surface.
We do not know the full history of these smuts
and it is likely that they are polymorphic also.
Please to observe the differences in their spores,
as shown in the figures. Those of *Ustilago
segetum* are rounded and somewhat flattened,
while those of the last species (*Ustilago May-
dis*), are rounded and covered with prickles.
Wheat is sometimes troubled with what is
called "bunt, or stinking smut." (*Tilletia caries*).
Wheat, affected with this fungus, changes its
appearance somewhat. The kernels are al-
ways large and a little green in color.

You take this in your finger, crush it and the
odor is exceedingly fetid. Under the micro-
scope myriads of little spores will be visible.
You will find that these spores are borne on
threads, and are very much reticulated. It
takes a power of three to four hundred diam-
eters to show these well.

Last year I made measurement of these
spores, and also measured an average kernel
of wheat. I find that

About Thirty Quadrillions

Of these spores are in each wheat kernel, and
now as each spore is capable of filling a whole
wheat plant, you see that means of reproduction
are exceedingly good in this case. Every wheat
plant seemed to be affected throughout. Wheat
grows in what we call "stools," first one stem
and soon little branches here and there so that
we will have four, five or six stems from one
kernel, each stem bearing a head of wheat. In
most cases if you find one head affected you
will find all the heads affected, which indicates
this: that these fungus growths affect all parts
of the plant; that if you wish to

Purify the Seed

You must apply the substances, or whatever
you do apply, to the seed itself. That is, in
treating certain wheat you must apply the rem-
edy there to the wheat sown. No doubt this
fungus disease begins when the plant is small.
The probability is that one spore is sufficient
to infest a whole stool of wheat; and as each
stool of wheat has at least three heads, you see
there is immense reproductive power. In the
figure here shown (figure 4); first, a head of
wheat, as it appears when affected; second, the

kernel of affected wheat, one of which is cut in two, showing the blackened and dusty interior; third, some of the spores highly magnified. In this fungus plant botanists have found the fertilization. This is interesting from the fact that for most fungus plants no fertilization has yet been discovered.

Without attempting a detailed explanation of the method of fertilization in this species, I will simply say that it is what is known as fertilization by conjugation; and is almost identical with what takes place in many of the seaweeds. The only point in the fertilization which we need notice is, that during the process, successive crops of very minute spores are produced. These minute spores are undoubtedly the bodies which enter into the stomates of the plants, and so propagate the species. These are exceedingly small and require a microscope of five or six hundred diameters to find them. From it again grows another smaller body that also has spores. This shows that Fungals have

Genuine Fertilization,

Such as the higher plants, which results simply from the union of two different cells. I will treat of remedies hereafter.

In the fifth of these orders the *Lycoperdaceae*; we have one plant of some interest, the *Lycoperdon*, the puff ball. Here is a specimen picked up alongside the walk coming from the horse cars. After a while this would become of the nature of a pulverulent substance. Under the microscope you would find a great many different little threads, and on these threads you would find spores. I do not exactly know what species this specimen is. Some species of *Lycoperdon* are used for eating. There is one that is called *Lycoperdon giganteum*—about as large as your head. This taken when perfectly white, sliced up like shoing a loaf of bread, and fried, is said to be exceedingly good. The caution in eating *Lycoperdon*, is never to eat it when it is in color. It is also used occasionally

For Staunching Blood

When a wound has been made. When a little of that is put in a wound, it staunches it very easily. I suppose that even a poisonous one would be good for staunching blood. Taking *Agaricaceae*, we have *Agaricus*. I show here the common one which is eaten, *Agaricus campestris*. The ring, which is found passing around it, is the remains of a covering that was once over it. Taking a gill, making a cross-section—a difficult thing to do, of course—and placing it under a microscope of high power, you will observe projections, which are simply longer and larger cells growing at right angles to the general surface. These cells bear upon their extremities four minute spores. So if you want to get the spores of these at any time, take a plant and lay it upon a sheet of white paper. The dust will be of the color of the spores—black, pink, white, purple, etc. The spores give the color to the gills. The species *Agaricus* are very general, there being many hundred species of them. You will find, usually, rules given as to the poisonous and unpoisonous kinds. These rules, I find, are of almost no use whatever, if they are based upon color. Very many times people choose pink-colored ones, but this will not do to rely upon implicitly. One kind of *Agaricus*, which is eaten in England and in Italy, is considered so poisonous as to be unfit for food; so you may be quite certain that there is nothing in those rules, and that you cannot place any dependence at all upon color. From a very careful examination, I am very certain that instead of any species being always poisonous or unpoisonous, its quality in this respect will depend very much upon surrounding circumstances; all of which have not yet been fully made out. These facts will show you that there is no dependence to be placed upon a certain species.

One more, the *Polyporus*, having a name indicating its character. In many of these upon the underside, instead of gills there are myriads of little holes. The spores are borne in just the same way as the *Agaricus*, but these spores are reflected back into little cavities instead of being distributed over the surface of the gills. Most of them have a one sided form, instead of being equal. Here in the middle of the stalk is one sided, so that they are more or less ear shaped. Many times you will find them growing upon the side of a leg, a sort of foreign growth. They have brown and white underside. Now the *Polyporus* is one of the greatest enemies that the engineer has to do with, or that any one who is putting up timbers has to encounter, because it sends mycelium through the wood, growing almost always on wood. Of course the mycelium is nourished by the wood. It is breaking down the tissues constantly, and brings about what we call rot. The railroad tie are probably thus injured. Instead of the decay being due to ordinary causes, it is due to the presence of *Polyporus* mycelium. Occasionally, if the timber is not in very damp soil, it decays with dry rot. Then you break the timber open and you will find mycelium. I have brought a specimen here to show you about what mycelium looks like. One or two other allied genera having the same characteristics, also produce the rot.

The fungus plants seem to possess a poisonous alkaline principle. Probably this principle is more due to some substance upon which the plants grow, difference in climate, dryness and all that, than to anything especially belonging to them. Now, as to certain rules which will make it safe to use them. First,

Never Eat any Bad Smelling Species.

Here smell is a good guide. By the way, that is a good guide, even for the *Campestris*. Second, they must always be perfectly sound. Now, this will require a knowledge of the species.

Fig. II.

Ustilago Segetum.—Head of Wheat, natural size.

Ustilago Maydis.—Blasted Indian Corn.

cies. Third, they must be perfectly white. In this they must not have begun their decaying state at all. Fourth, in cooking they must always be sufficiently cooked to make them tender. If they are tough, they are not eatable.

Fig. IV.

Tilletia Caries.—Head of Wheat affected with Burnt or Stinking Smut.

Fifth, as they are a sort of concentrated food they must always be eaten with moderation. They take the place, very largely, of the muscular parts of animals, in supplying nu-

Fig. V.

Agaricus Campestris.—Edible Mushroom.

tritive qualities, much more than does the ordinary use of vegetables.

A student asks, "What is that silver spoon test?" Professor—"I do not know of that at

all. I do not know what that would indicate at all. I do not know anything, about the plants, that would make it a good test." Student—"It is nearly always used, especially among the French people." Professor—"It

Fig. III.

Ustilago Maydis.—Blasted Indian Corn.

may have reference to the soundness of the spores. If the development is beginning to rot, possibly the spoon would be darkened, simply by the dark-colored spores." Then, as a note after these rules, it must be remembered

Fig. V.

Agaricus Campestris.—Edible Mushroom.

that some people can not eat them with safety. There are some peculiarities of constitution that will not admit of their use, and what that is may be difficult to describe, so that each man must be an experimenter in this for himself. The gist of these rules may be put down as this: That you must

Go at them very Carefully.

If you are very cautious, I do not see why you may not be able to use them. I would say, however, it will hardly pay you to try the dark-colored ones. They seem to purify so soon it will hardly repay your trouble.

The fungus plants, with a few exceptions, are of little account medicinally. In Northern Asia, one species is used very largely in procuring intoxicating drink. Another, in certain parts of Europe, is mixed with pepper and made into a certain sort of snuff. There are certain other species which have a brilliant color, from which is extracted a dye. In part of Germany, some mycelium of the *Polyporus* is collected, poured up and used as a tinder, usually mixed with sulphur or something like that. Another species, usually grow in thick, fey masses, and this felt is used as material for clothing, so that we actually have the fungus plants furnishing clothing.

Fly poison is manufactured from another species of *Agaricus*.

This green color, which is frequently found in oak wood (in cutting up an old log of wood you will frequently find a green color), is due to mycelium. This plant departs from the usual law of the fungus plants. This green is a sort of metallic green. In certain parts of Africa, the natives have such high regard for these plants that one is deified and

Worshipped as a God.

Phosphorescence on decaying wood is simply the rapid decay brought about by the presence of a great amount of mycelium. Blood red drops, which frequently have been referred to rains of blood, must be referred entirely to the presence of minute fungus growths.

A few years ago, the bakers in Paris were astonished because the bread was found very frequently to be covered over with

Blood Red Drops.

The people were somewhat superstitious, and it caused a great deal of alarm. Careful investigation showed it to be simply a fungus growth. Contagious diseases have sometimes been induced by rubbing the spores of some of this species upon the skin. These, as you observe, are simply disjointed facts.

Dry Rot

May be very easily prevented by using gas tar, corrosive sublimate and sulphate of copper; or any of the processes, of course, which keep out these spores. Painting, when well done, and oiling, would serve equally as well as long as it lasts.

Botanists have a great many times called attention to the fact that the same species of tree will not grow well where it has been cut down. The remark has been frequently made that hard wood requires to be replaced by soft wood and these again by hard wood. The explanation is probably due to this: That the mycelium which destroyed the roots and prevented their growth, will attack the more recent growth. Perhaps it will better explain the fact to state that if any of the orchard trees—for instance an apple tree—is killed in the same way, it is quite difficult to start a young apple tree in the same place; because the same mycelium which destroyed the old, will attack the young apple tree roots, and, of course, destroy the tree. I suppose the species which does the mischief belongs to this group, the *Polyporus*.

The mildews and blights which are found upon the leaves of plants may be treated with sublimated sulphur. We do not know just how this is; for sulphur is largely insoluble; yet simply sprinkling it over very soon destroys this fungus growth, and the plant will be saved; or, if any of the soluble forms of sulphur are used you will find, in almost all cases, good will result. So, of course, sulphate of copper or any of the sulphates are good.

For bunt or smut (*Tilletia caries*) in wheat the seed should be washed in water, brine or hot lime water. A more certain remedy is to steep the seed in a strong solution of sulphate of soda (glauber salts) and then to dust it with quick lime. Sulphate of copper (blue stone) dissolved in water and sprinkled over the seed, is another remedy relied upon by farmers.

In general moulds and mildews—all these small growths here—do not flourish well in dry places. If you have a place that is affected simply dry it, let sunlight into it, and they will very largely disappear, either mould or mildew. Really there is no need of any of these being found in any of our houses.

The Rain Fall.

We give below a report of the rain fall to date from all the localities in the State, from which we have thus far been able to obtain the same. We shall add to this list reports from other localities as they may come to hand:

Our Rain Gauge.

DEFERRED.—As we desire to publish in full the lecture delivered by Dr. Becker last Saturday at the Mechanics' Institute on "Quicksilver and Fuel," we are obliged to defer its publication until our next issue.

COAL retails in Virginia at present, at from \$22 50 to \$28 per ton. Wood retails as follows: Nut pine, \$16; limb wood, \$15; tamarack, \$15; Carson split wood, \$14; Empire split wood, \$12; stove wood \$6 to \$8 per cord.

The recent rains are reported to have damaged the ditches and reservoirs of the California Water company in El Dorado county, to the extent of over \$30,000, one large reservoir costing \$25,000 being entirely swept away.

THERE are thirteen furnaces for smelting quicksilver ore, running or nearly ready for work, in Sonoma County.

QUARTZ mine in this section, says the Placer Herald, are all running full forces with favorable results.

THE TEXT BOOK MATTER.

A Statement by the Publishers of the Pacific Coast Series of Readers.

Many incorrect statements having been made with reference to the changes in text books, recently ordered by the State Board of Education, we desire to submit to the public the following facts:

On June 22, 1874, the State Board of Education advertised for proposals for new text books, said proposals to be in by January 5, 1875.

In response to this advertisement, twelve Eastern houses and one California house came forward with proposals and samples.

Of all the changes proposed by these several competitors, the Board made but three, viz:

First—The Pacific Coast Readers were adopted in place of McGuffey's.

Second—The Spencerian Penmanship was adopted in place of the Payson, Dutton & Scribner Series.

Third—Cornell's Geographies were adopted in place of Monteth's.

These changes were made by the following vote: Readers—Ayes—Allen, Denman, Kelly, Kennedy, Lynch, Noes—Bolander, Booth, Crawford, McMeans.

Penmanship—Ayes—Allen, Bolander, Crawford, Kelly, Lynch, McMeans. Noes—Booth, Denison.

Geographies—Ayes—Allen, Bolander, Booth, Kelly, Kennedy, Lynch, McMeans. Noes—Crawford, Denman.

We give below copies of the proposals for Readers and Geographies, that the public may see what publishers have dealt generously with them, and what members of the State Board have kept most steadily in view a consistent regard for the interests of the people and of the schools.

We make no mention of the Penmanship, as a gradual change in copy books is evidently attended with no expense.

The publishers of the Pacific Coast Readers submitted the following proposals:

SAN FRANCISCO, January 5th, 1875.

To the Honorable the State Board of Education of the State of California: GENTLEMEN: In accordance with the resolution passed by your honorable Board on June 22, 1874, we submit the following proposal:

First—We will supply the Pacific series of Readers at the following prices, viz: First Reader, 20 cents; Second Reader, 35 cents; Third Reader, 55 cents; Fourth Reader, 60 cents; Fifth Reader, \$1. These retail prices shall hold good in San Francisco for the whole four years for which the books are adopted, and to enable dealers throughout the State to sell at the same figures, we will give them a reasonable discount from the prices herein named.

Second—We will also give our books in even exchange for McGuffey's, as follows: Pacific Coast First Reader for McGuffey's First Reader; Pacific Coast Second Reader for McGuffey's Second Reader; Pacific Coast Third Reader for McGuffey's Third Reader; Pacific Coast Fourth Reader for McGuffey's Fourth Reader; Pacific Coast Fifth Reader for McGuffey's Fifth. Books sent for exchange to be in sufficiently good condition for continued use in school and accompanied by a certificate from the teacher or school officer that the books offered for exchange are the property of a pupil and designed for use in school by said pupil. In order to secure the full benefit to the people throughout the State and avoid all expense of a change, we agree to establish one or more depots of supply in each county, to which we will send the books at our own expense, till such time as the use of the books become satisfactory under the action of your Board; and we further agree to make such even exchanges at our place of business for and during the whole four years covered by their adoption.

Third—We guarantee that the stock supplied shall be in all respects as good as the samples presented, and we agree to replace at our own expense, during the entire four years, any book sent to us which has become worn through defect in binding, or which is defective in arrangement of signature, or in any other respect in which we, as manufacturers, are properly responsible.

Fourth—We hereby agree that the press work and binding of our books shall be done within the State of California for and during the whole four years covered by their adoption.

(Signed) A. L. BANCROFT & Co., SACRAMENTO, JANUARY 5, 1875.

At a reasonable discount we hereby agree to give to the trade throughout the State a discount of not less than 20 per cent. from the prices named herein, and an additional discount of 10 per cent. to the wholesalers.

(Signed) A. L. BANCROFT & Co., Per Dorville Libbey, Attorney.

The proposal for Cornell's Geographies was as follows:

Cornell's Primary at 75 cents; Intermediate, \$1.25; Physical, \$1.48. Discount to the trade same as in case of Readers. Agencies to be established at San Francisco, Sacramento, San Jose, Stockton, Oakland and Santa Rosa. Introductory exchange as follows: Cornell's Primary, for Monteth's Introduction and 45 cents; Cornell's Physical, for Monteth's Physical and 90 cents.

By comparing these proposals it will be seen that the Publishers submitted to the people in exchange for McGuffey's, absolutely without expense, while for the Geographies (always the most expensive of common school text-books) the pupils must pay 45 and 90 cents, respectively, besides giving up their Monteth's Geographies. Indeed, the publishers of Cornell were prevented by the Eastern Publishers' Board of Trade, of which they were members, from offering more liberal terms on their books, even if they desired to do so.

We do not make these comparisons particularly as against the adoption of Cornell's Geographies, for which we presume the Board of Education had the best of reasons. We desire merely to show the injustice of the criticisms upon the Board for the adoption of our Readers, while the change of Geographies remains unchanged.

The very parties who now seek to put themselves forward as guardians of the public interest, and against a home industry which costs the people nothing, and for a change in Geographies, made in New York, which will be a tax upon every pupil in the State.

A careful analysis of our proposals will show:

First—That the prices of our Readers are 15 cents per set less than the prices at which McGuffey's were adopted four years ago, and at which they have been sold up to the present time.

Second—That we agree to give our books for McGuffey's old ones, without expense to the pupil, and that we will organize distributing agencies and give every facility for such exchanges during the whole four years.

Assuming the cost of the readers now in the hands of the pupils at \$4,000 (not \$250,000 as frequently quoted), and assuming that the stock is worth one-third less now from use and wear, we have over \$13,000 actual gain to the people by the exchange of the old books for the new.

Third—That we agree to replace, at our own expense, any of our books defective in manufacture, a guaranty never given in this market by any Eastern House.

Fourth—That the books shall be manufactured within

in our own State during the entire period covered by their adoption.

Fifth—That we make the same terms to the trade as all the Eastern houses.

We leave the public to judge whether a proposition so liberal for an important home industry deserves the violent and malicious attacks which have been made against us, incited by parties whose private interests were ignored by the Board of Education in favor of the interests of the people.

As to the merits of the Pacific Coast Readers, we ask the public to consider the following endorsements:

First—The County Superintendents of California. We sent a circular and a set of Readers to all the County Superintendents, asking for their "opinion of the book and our enterprise." We received in all 38 replies; 37 of them indorsing our books very heartily, and one indorsing McGuffey's in preference to ours.

Of the 37 indorsing our Readers, 14 distinctly ask for a change from McGuffey's to the Pacific Coast Series; and the remaining 23 either remain silent about a change or object solely on the ground of expense, or declare that a change will be desirable if it can be brought about without expense.

The originals of these letters are all on file in our place of business, and we shall be glad to have any one call and examine them and verify this statement.

The assertion was made at the meeting by Superintendent Bolander that "Thirty-four of the forty-seven County Superintendents had sent in a remonstrance against a change."

It is noteworthy that he did not name them or offer to produce the documents, and, in view of the facts, we can only suppose that he accidentally said "against" instead of "for."

Second—Our books are indorsed by leading teachers throughout the State. Their indorsements were submitted to the Board, and can now be seen at our place of business.

Besides these, we presented to the Board another class of indorsements, bearing upon our enterprise as a home industry, viz:

First—From the State Grange of the Patrons of Husbandry, unanimously and enthusiastically adopted at their meeting in October, 1874.

Second—From a large number of local Granges.

Third—From the Mechanics' State Council.

Fourth—From leading and representative business men of San Francisco.

This document will be given in full to the public, to show what leading citizens think of our enterprise.

Against all this array of favorable opinion we have, so far as we know, the opinion of but one educational man, viz: Superintendent Bolander, who enters his "solemn protest" against the Pacific Coast Readers as "inferior in contents, presswork, binding," and, indeed, in every particular.

After an eager and microscopic search for errors to justify his opposition to the books, Superintendent Bolander, in the meeting of the Board made a few remarks which the Governor and his fellow members unanimously pronounced "hypercritical" and "unworthy of consideration."

On the other hand, so far as we know, not one indorsement of McGuffey's Readers were read or referred to in the meeting.

The public will surely remember how severely McGuffey's Readers were criticised at the time of their adoption four years ago, and later, in the interests of Mr. Bolander, in the election of 1871. At that time they were "relics of ignorance," "superannuated rubbish," "compliments of disloyalty," "pup and piety," and everything else that could be said derogatory to them.

The books have not been changed in a single word since then; public opinion is just as it was then; and yet now, strange as it may seem, we find Superintendent Bolander their special advocate; and that, too, against a better series, made at home, and offered at terms unprecedentedly favorable.

In conclusion we have only to say that we know that we are engaged in a legitimate and commendable business, of great importance to the State; that we have made excellent books, fully worthy of use in our schools; that they have been fairly and legally adopted by a competent Board of Education; that no expense whatever is caused by their introduction; and we appeal to the sober second thought and the disinterested common sense of the people for our justification.

TEATS' PATENT FURNACE.

TEATS' PATENT FURNACE

For Roasting, Desulphurizing, Chloridizing and Oxidizing Ores, etc. For the reduction of Gold, Silver, Lead and other ores, saving a larger percentage, at less cost, than any other invention now in use. Chloridizing Silver ore more thoroughly, in less time, with less fuel, salt and labor; also roasting Lead ore preparatory to smelting, better and cheaper than any other invention. The Furnace is so constructed that one man, of ordinary ability, tends five or more furnaces; controls them with ease; adding heat or air; stopping or starting at will; charging and discharging with ease. Also, Patent "Conveying Cooler," for conveying and cooling roasted ores, heating the water for amalgamation and the rollers at the same time. Saving the large space in mill (covered with brick or iron), and the labor of two men per day, exposed to the poisonous chlorine gases. Also, Patent Air Blast "Dry Kiln," for drying ores direct from the mine or breaker, saving fuel and labor heretofore necessary in drying ores for dry pulverizing. For description refer to Mining and Scientific Press, No. 18, October 31, 1874. For particulars address D. B. MILLER & CO., No. 12 West Eighth Street, Cincinnati, Ohio Circulars, etc., will be furnished, if required. 18v29-3m

STEEL SHOES AND DIES

FOR QUARTZ MILLS, Made by our improved process. After many years of patient research and experiment we have succeeded in producing STEEL SHOES AND DIES FOR QUARTZ MILLS, which are unequalled for Strength, Durability, and Economy

Will wear three times longer than any iron Shoes BUILDERS AND CONTRACTORS

Of Quartz Mills, Pans, Separators, Concentrators, Jigs, Hydraulic Rock Breakers, Furnaces, Engines, Boilers and Shafing, and general Mining Machinery in all its details and furnishes of Mining Supplies. All orders promptly filled. MOREY & SPERRY, 88 Liberty street, N. Y. Examination solicited. 9v28-1y

EAGLE IMPROVED CHLORINIZING AND DESULPHURIZING FURNACE.

(Patented July, 1873.) The Cheapest and Most effective Furnace now in use Parties desirous of building above furnace, or for any information on same, address, I. T. MILLIKEN, 331 No. 302 Montgomery st., room No. 14, S. F.

Stamp Mill For Sale at Ophir Canon, Nye County, Nevada. Midway between Austin and Belmont, belonging to the Twin River Consolidated Mining Co. A complete mill, comprising twenty (20) 800lb stamps, (dry-crushing) with Rock Breaker, Pans, Settlers, and entire outfit of milling appliances; together with an excellent engine (18x42), two tubular boilers and all requisite shafting, gearing, belting, &c., a valuable lot of Sierra Nevada timber in Battery frames and building. The whole is offered cheap. For further information apply to JAS. D. HAGUE, 17v28-3m 240 Montgomery St., S. F.

STEAM ENGINES AND BOILERS Of all sizes—from 2 to 60-Horse power. Also, Quartz Mills, Mining Pumps, Hoisting Machinery, Shafing, Iron Tanks, etc. For sale at the lowest prices by J. HENDY, No. 32 Fremont Street. 10v27tf

CROCKER'S PATENT TRIP HAMMER QUARTZ BATTERY.

This machine, complete, weighs 1,500 lbs. Has an iron frame, five steel arms with stamps weighing 17 lbs. each, which strike 2,000 blows per minute, in a mortar provided with screens on both sides, and crushes FINE 600 lbs. per hour, requiring one-horse power to drive it. Has been thoroughly tested, and is guaranteed to give good satisfaction. PRICE, \$800. G. D. CROCKER, 17v28-1f 315 California street, San Francisco.

JOHN TAYLOR & CO., IMPORTERS OF AND DEALERS IN ASSAYERS' MATERIALS

Chemical Apparatus and Chemicals, Druggists' Glassware and Sundries, PHOTOGRAPHIC GOODS, ETC., 512 and 514 Washington street, SAN FRANCISCO

We would call the special attention of Assayers Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our large and well adapted stock

ASSAYERS' MATERIALS Chemical Apparatus, Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast.

Our Gold and Silver Tables, showing the value per ounce Troy at different degrees of fineness, and valuable tables for computation of assays in Grams Grammes, will be sent free upon application. 7v25-1f JOHN TAYLOR & CO.

Varney's Patent Amalgamator. These Machines Stand Unrivaled. For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits. They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows: The pan being filled, the motion of the muller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces.—Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing a regular row between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Sellers made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill-men are invited to examine these pans and settlers for themselves, at the office, 229 Fremont Street, San Francisco.

Nevada Metallurgical Works, 21 First street.....San Francisco.

Ores worked by any process. Ores sampled. Assaying in all its branches, Analysis of Ores, Minerals, Waters, etc. Plans furnished for the most suitable process for working Ores. Special attention paid to the Mining and Metallurgy of Quicksilver.

BALL'S SWEEPING DREDGE,
A NEW AND VALUABLE
CALIFORNIA INVENTION.
Has been very lately well proven by performing a job of dredging at the mouth of San Antonio Creek, at Oakland, Cal.

There is but this one machine that has ever had these improvements employed. It is an old machine, formerly built for another device, and is unfavorably constructed for Ball's improvements; yet this first temporary experimental machine has filled a scow of eighty-five cubic yards in sixteen minutes in unfavorable digging. For durability, digging hard material and fast work, it has a reputation (supported by leading engineers) as having no equal.

Testimonials and references will be given on application to the inventor, who is the sole owner of patents (excepting having made an assignment of the one machine now belonging to the Central Pacific Railroad Company) Having resolved not to sell any rights unless upon a basis of actual work performed by a machine built by myself for the purpose of fairly establishing the worth of the invention, I therefore offer to sell machines or rights on the following plan, which is warranting the capacity of the machine by actual work:

I will enter into an agreement with any responsible party to build and sell a machine, scows and tender, all complete, and right of all my improvements in dredging machines throughout the Pacific Coast for \$20,000, warranting the machine to dredge six cubic yards per minute (to fill a scow at that rate). \$20,000 will but little more than pay the cost of building the machine, scows, etc., all complete; therefore I am proposing to ask nothing for my patents unless my machine dredges more than six cubic yards per minute. But it shall be further agreed that in case (at a fair trial to be made within a stated time) the machine shall fill a scow at the rate of more than six cubic yards per minute, then \$10,000 shall be added to the price above stated for each and every such additional cubic yard thus dredged per minute, and for additional fractions of a cubic yard thus dredged in the same ratio the \$10,000 is to be added to said price above stated.

I will sell any other Territorial or State rights (either United States or Foreign) upon the same plan and at a lower price proportionately than the rights for the Pacific Coast.

I will sell a single machine with scows and all complete, and right to use the same in a limited territory, for \$20,000 on the same plan as above stated, but will add only \$2,000 to each additional yard over the six cubic yards per minute. Each machine is not to employ more than two 10x20 inch engines.

Payments to be made in U. S. gold coin on delivery of machine, as may be indicated by agreement.

Address, **JOHN A. BALL,**
Oakland.

N. Seibert's Eureka Lubricators.

THE HIGHEST PREMIUM

Awarded by the Mechanics' Institute Fair, San Francisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers to be superior to any they have ever used: feed constantly by pressure of condensed water supplied by pipe A, regulated under the oil by valve J, and forced out through check valve and pipe B into the steam pipe C; it then becomes greasy steam, passes to all the valves and cylinder at every stroke of the engine; glass tube I indicates amount used per hour. Packing on rods and stems lasts longer, and the rings on the piston will not corrode. One pint of oil will last from three to six days, according to speed and size of engine; I, sliding gauge; K, valve to shut off when engine stops; H, F, valves to shut off in case of frost, steam does not enter the cup; it is always cool; warranted to give satisfaction. Patented February 14, 1871. Manufactured by California Brass Works, 125 First street, S. F. 24v23

Hydraulic Mining in California.

No. 11.

Water Ditches.

The ditches of California are the great arteries which bring life to the mines. Their even and constant flow secures a healthy and vigorous state of industry, while the dearth of water in the mines throws a pall over the business world of California, money becomes tight, and hard times are the consequence.

The engineering skill displayed in the construction of ditches in this State is of the highest character, accomplishing the most daring feats, hanging flumes on steep, rocky bluffs, and crossing gorges of a thousand feet in depth; and it must seem almost a presumption to inquire whether any improvements can be suggested.

Leaving the answer to this question open for the time, we will try to state the rules and conditions which justly have governed the constructions of ditches.

Location.

The first among them must be the ample supply of water during all seasons of the year. When this steady flow can be secured, even at a greater outlay of money, let it be done by all means. The winter supply of water is well enough, but the summer supply is far preferable, as the working of a hydraulic mine then has the advantage of long days, mild weather, and water made almost tepid under the rays of a hot sun. The latter point is the most important, as the quicksilver catches the gold far more easily at a high temperature than in cold weather. The yield of gold, therefore, increases always in the summer season, other conditions being equal.

The second condition must be the high elevation of the ditch. A ditch of high elevation commands a greater field of usefulness, as it may supply mines for which it was not constructed, when the original mines are exhausted. Besides this, the increased hydrostatic pressure is always valuable.

The snow line should be avoided, if practicable; but snow-sheds can be constructed, though in some regions this might involve a great expenditure. Pine boughs, laid thickly across sleepers from henk to bank, have been used with good effect, as the snow rests on them and forms finally an arch, supporting itself.

A third important point is to secure all the small water courses on the line of the ditch in such away that they can either empty into the ditch or run over it, according as their water is needed or not.

A fourth important condition is the abundance of waste gates, and their location in places where the discharge of water cannot wash the ground below the ditch, so as to produce a slide. This will permit the prompt drainage of the ditch whenever a break makes it necessary.

Fifthly, the building of flumes should be avoided so far as practicable, since they are liable to be destroyed by fire. When they have to be built, care should be taken to char well the bottom part of the supporting posts or sleepers, so as to prevent the rot. The settling of flumes, due to the decay of the bottom of the posts, or the sleepers upon which they rest, causes a great deal of annoyance.

Experience has shown in many cases that the above mentioned rules deserve close attention in choosing a route for a ditch, as the advantages or disadvantages pointed out can be weighed carefully beforehand.

Construction.

The building of a ditch can commence after a careful survey has been made. A grade of 10 feet per mile (three-eighths inch per rod) ought to be established by the survey, as this grade has proven itself the most convenient for the conveyance of water, securing an excellent flow, without endangering the banks of the ditch. This grade must be adhered to strictly, and under no circumstances must it be lessened at one point and increased at another, since the flow of water, once checked by less grade, cannot be regained by increasing the grade at another point. The ditch in such a case would have to be widened.

Condensed from an article by Charles Waldeyer, of the last Annual Report of the U. S. Commissioner of Mining Statistics.

Industrial Items.

INDUSTRIAL IMPROVEMENTS AT MOUNTAIN VIEW STATION.—The San Jose Mercury, Jan. 30th says: The people of Mountain View Station are happy now that Watkins & Co. have located their foundry and machine shop at that place. Operations will commence at once. The stockholders are J. T. Watkins & Co., G. W. Smith, J. Snyder, D. B. Beale, Castro & C. Ideron, W. H. Bubb, H. D. Magot, J. Heaverty, and H. McCleary all men of means.

There is talk of a flour mill being put up here this summer. If so the company will run a steamer from C. Guthe landing to San Francisco. It is only two miles from the Station to deep water in the bay. Mr. Guth is making preparations for digging a canal to high water.

THE BAMBOO.—Has anybody ever tried to grow the bamboo in this country? There are about sixty varieties of this valuable tree, and it would seem that some of the more hardy varieties might be made to grow in California.

FOREST TREE SEEDS.—The gathering and sale of forest tree seeds, is becoming quite a business in California. Messrs. Stegman & Sons of Yosemite valley, sell annually 200 pounds of the seeds of the Big Tree, *Sequoia Gigantea*. Each pound contains 120,000, so that the total number of seeds planted every year may be estimated at nearly twenty millions. They go to all parts of the world, and it seems that the ornamental gardens of Europe and the Asiatic states should soon have enough of them.

LAMP CHIMNEYS.—The Titusville Courier says: Two thousand Pittsburgh glass-blowers are constantly employed in the manufacture of lamp chimneys for the trade. These chimneys are warranted to break quicker by sudden changes of temperature than any others turned out elsewhere, and thus the trade is benefited. Judging from our personal experience we should suppose that a large invoice of these chimneys must have been received in California.

INDUSTRIAL SAVINGS.—The eleven savings banks of this city have now 60,658 depositors. The total amount of their deposits is \$55,021, 177; this is an average of nearly \$900 to each depositor. Their net earnings of this money is at the rates of 8 to 9% per cent per annum. There has been an increase of 4,947 in the number of the depositors within six months, and of \$4,160,915 in the amount of deposits.

NOVEL ROAD VEHICLE.—Twenty-four small two-wheeled vehicles have been constructed by the Kimball Manufacturing Company for use in China. They are to be drawn by Chinamen, and will each comfortably accommodate one lazy Caucasian.

HEALDSBURG offers \$10,000 for a supply of water. This is a fine opportunity for enterprising capitalists.

A POTTERY is to be established at San Bernardino. Superior clay for the purpose exists there.

General News Items.

SENSIBLE.—Carlyle has declined the Order of the Grand Cross of Bath, which was offered him. The Baronetcy tendered to Tennyson has also been declined, to protect his honor. Bismarck, it will be recollected, refused to receive his title of "Prince" unless it was coupled with the name with which his fame had up to that time been connected. The Emperor, after some hesitation, acceded to his wishes.

LOCKEN OUT.—News comes from London that 120,000 men are thrown out of employment in the dead of winter as the result of a coal-miners' strike in South Wales. How much better would it be for all governments to follow the example of France in establishing courts of arbitration for the settlement of labor quarrels, by means of which, in ninety-five cases in a hundred, there is a reconciliation between the parties.

PROTECTION TO SETTLERS.—Luttrell has, or soon will introduce a bill for the protection of settlers; providing that whenever any railroad is granted permission by Congress to change its location, all land originally granted to it shall be forfeited and become subject to the homestead and pre-emption laws.

SINGULAR DISCOVERY.—Fourteen pounds of mutilated bank bills, of various denominations, representing over a million dollars, have been discovered in a rag shop at 411 West Twentieth street, Washington. They are of various denominations with large pieces cut out of the center. No one seems to know anything of their history.

A SCIENTIFIC HOAX.—Several of our contemporaries have been hoaxed with a pretended calculation, based upon observations of the late transit of Venus which demonstrates that in 1,400 years the earth will fall into the sun and of course be destroyed. The New York World started the story.

ENCOURAGING THE CULTIVATION OF FOREST TREES.—Among the laws passed by the Idaho Legislature is one to encourage the growth of forest trees, which exempts the grower of five acres or more of forest tree from taxation on \$100 of his property for each acre planted in trees.

CALIFORNIA APPROPRIATIONS.—The Congressional Committee on Appropriation will report favorably on the following appropriations: For improvements in California harbors—Oakland, \$100,000; San Diego, \$80,000; Sacramento River, \$25,000.

NO TROUBLE WITH SPAIN.—By dispatches from Madrid, it is quite evident that no trouble is to be apprehended in settling the 'Virginian' difficulty with Spain.

ECLIPSES.—There will be two eclipses of the sun this year. One, April 6th, not visible in the United States; the other, September 29th, visible east of the Mississippi.

BANDIT THREATS.—The people living in the southern portion of Monterey county are afraid of Chavez, and are arming themselves to be ready for him should he make a raid among them.

THE SAW MILLS in Inyo county have been compelled to suspend operations, on account of the deep snow in the timber where they procure their logs.

"THE KING" left San Francisco on Tuesday last for his island home.

A PROPOSED HOSPITAL.—The Napa Register states that the German Benevolent Society of that city are contemplating the establishment of a hospital in Napa valley. Convalescent patients will employ themselves in weaving baskets from the willows in the vicinity.

FLOUR MILL DESTROYED.—The uncompleted flour mill located in Putah cañon, a short distance above Wolfskill, was washed away by the late heavy rains. Not a vestige of the mill remains.

Agricultural Items.

THE HARVEST OF UTAH.—The quantity of wheat harvested in Utah was 30 per cent. less during 1874 than the previous year. Barley was 10 per cent. less; oats, 7 per cent. less; Indian corn, 15 per cent. less; potatoes, 8 per cent. more; hay, 7% per cent. less. Dried peaches, in consequence of an unusually large crop, footed up nearly four times as much in 1874 and 1873. There was an increase of 50 per cent. in eggs, butter and poultry, and the number of hogs, beehives and sheep raised was considerably in excess of 1873.

FISH CULTURE.—The Plumas National says: Henry Landt, of the Big Meadows, has several men at work constructing a fishery, which he designs making one of the most extensive operations of the kind on the coast. The Big Spring, in the Meadows, is the basis of the operations, and large ditches, now being dug, are to lead the waters of several of the mountain streams into the spring, giving the trout an extensive range.

ALDEN FRUIT DRYER IN SONOMA.—The results of the working of the Alden fruit drying enterprise, which was established last year at Sonoma, have proved very highly satisfactory; so much so that the company contemplates enlarging their works for the operations of the coming season.

SALINAS RIVER CHANNEL.—The Captain of the steamer Salinas reports that the recent rains have quite changed the channel at the mouth of the river Salinas, and estimates that it has been shifted at least 1,000 yards from its former position.

GOAT RAISING.—C. S. Abbott, Flint, Bixby & Co., and B. Boswell have purchased most of the stock of the Guadalupe Island Company, and purpose going extensively into the business of goat raising.

LOS OF SHEEP.—Haggin & Tevis are reported to have lost between 1,500 and 2,000 sheep by the recent flood. The animals were grazing on the Norrie Ranch.

GROUP DISEASED BY ITS TERRORS.—The group cough, so alarming to the ear and so dangerous to life, to which children are subjected, may be immediately relieved by administering a dose of *Hale's Honey of Hyaloid and Tar*. When given to a child who seems to be choking under the effects of a spasmodic and husky cough, the effect is electrical as many a mother will testify. In fact there is no affection of the throat or the lungs, short of the actual disorganization of the tissues and membranes, which it will not cure. *Pike's Tooth-Ache Drops*—One in one minute.

TO COPPER SMELTERS, BLUE-STONE

& SULPHURIC ACID MANUFACTURERS.

For sale or to lease the **LEVIATHAN COPPER MINE**, in Alpine county, California.

The ore, which is in the form of silicate, black and red oxide, and gray sulphide, with metallic copper finely disseminated, averages from two to five feet thick, and 15 to 50 per cent. copper. A few parcels taken out during exploratory operations, realized \$30,000 for Bluestone. In sight, 2,000 tons 20 per cent. ore; on dump, 300 tons 15 per cent. Supply inexhaustible. Title perfect. Minimum present capacity, 10 tons per day, which may be extended indefinitely. Cost of extraction, \$2. There is also a stratum of sandstone 20 feet in thickness, impregnated with 26 per cent. pure sulphur. To a coin purchaser highly advantageous terms will be offered. For further particulars apply to Lenre Chalmers, Silver Mountain, Alpine county, Cal.

WATER TANKS of any capacity, made entire by machinery. Material the best in use; construction not excelled. Attention, dispatch, satisfaction. Cost less than elsewhere.

Descriptive Circular
and Prices.
SEND FOR

COOK, RYMER & CO.'S Celebrated Hoisting Engines have been too long in use on the Pacific Coast to require any special recommendation from us. We refer with confidence to any one of the hundreds now in use. We stoutly state that they still sustain their old reputation, the manufacturers not having followed the now too common practice of reducing the quality of material and workmanship for the sake of competing with cheaper engines. For details of sizes send for price list. We desire to call particular attention to our new

MINING HOISTING ENGINES.

(Manufactured by the same parties.)

Which have just been introduced on this Coast. The plans and specifications are the combined efforts of our most successful MINING ENGINEERS, and the result is the most complete

DOUBLE-DRUM HOISTING ENGINE

Ever built. Their advantages will be seen at a glance by any one familiar with the necessities of a mine. One of these engines may be seen at work in the Belcher mine, and one in the Ophir, on the Comstock lode, to both of which we refer. We have all sizes of these engines constantly on hand. For sale only at

Stationary
ENGINES.

FOR
Steam Pumps
AND
Hot or Cold
Water Pumps
OF ALL KINDS.

The CENTENNIAL is composed of the finest Hemp, made in strands or sections, of different sizes, each being saturated in a composition of pure German Black Lead and Tallow and covered with a braiding of the best Italian Hemp to be found in the market. It is manufactured in a shape the most convenient to use and handle, and gives from 50 to 100 per cent. more length compared with an equal weight of other makes. It runs with less friction on the rod than any other Packing made, from the fact of its being so perfectly soft and pliable, and so well lubricated so to require a minimum pressure on the rod. It cuts off smooth and makes perfect joints, is easily adjusted to any size rod, and only requires occasionally a new ring to keep the stuffing box full. ENGINEERS, TRY IT. For sale in any quantity by TREADWELL & CO., San Francisco.

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

[PATENTED MAY 26TH, 1874.]
Price Reduced to 18 Cents Per Pound.
SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally.
We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburgh Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES AND DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent. cheaper than the best iron. There are no STEEL SHOES AND DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES AND DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES AND DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappets, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 60 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to

CAST STEEL SHOE & DIE CO., Room 1, Academy Building, S. F.

IMPORTANT TO LUMBERMEN.

\$100.00 IN GOLD.

And FIRST PRIZE SILVER MEDAL were awarded to us for the best

SAWS

In the great National contest held at Cincinnati, September, 1874, and lasting over six days. Our celebrated DAMASCOUS TEMPERED SAWS were declared the victors.

We have made special shipping arrangements for very low freights and quick dispatch of our saws for the Pacific Coast. **ONLY SEVEN DAYS BY MAIL FROM SAN FRANCISCO.** Send your address for a full report of the great National Sawing Contest, and the class of saws that you use, with the thickness, size and kind that you use, and specify such as you will require within the next 60 days. We will guarantee to furnish you with saws that have no equal in quality, and at prices that will be entirely satisfactory. Address

Cazin's Combination Ore-Sizer and Con- centrator—One Plunger System.

(Covered by Letters Patent of July 24, 1872, and recent applications.)

Containing a sizing apparatus, (revolving screen) deliv-
ering two or four sizes of ore to two or four rows of
sieves, each row independent of the other, and each
having 5 sieves, each row concentrating according to
specific gravity the special size automatically fed into
it, resulting in the simultaneous continual delivery of
separated materials, working 2d and 3d-class ores into
1st-class ores of perfect cleanliness. It thoroughly se-
parates native gold or copper from quartz or any other
lode matter—galena and silver sulphurets from
pyrite, barytes and quartz; and pyrites from quartz.

Added to a battery of stamps these machines consti-
tute a full system of ore concentration, sufficient in
most cases for the requirements of western mines, with
a capacity of 15 or 20 tons per 24 hours.

For particulars apply to,

F. CAZIN, M. & C. E.

Supt. Denver Concentration and Smelting Co.

Number 7.

Low Water Alarm Gauge.

The accompanying cut represents Weldon's patent low water alarm gauge, which is now being introduced on this coast. The invention consists of a hardened float and the arrangement of a lever, valve and fulcrum in such a manner that it is impossible for it to hind or get out of order. As will be seen by the cut the float is at one end of the lever and fulcrum at the other, and the valve being close to the fulcrum, gives the float sufficient leverage when the water leaves it, to open the valve and blow the alarm whistle under 1,000 pounds pressure, which is more than any steam boiler will stand. The float is hardened by a new process, which leaves it perfectly round and smooth, and is tested outside and inside by a hydraulic pressure of 500 pounds to the square inch; it is then plated with nickel, so that the steam cannot oxidize the spelter. No float of this patent ever can collapse or fail; it is not necessary to shut off the gauge or take out the float while testing the boiler, for the float will stand more pressure than the boiler. The valve passes through the lever near the fulcrum, and is held in position by little adjustment nuts, and is guided to its brass seat. The valve, lever, fulcrum and valve seat are made of the best steam metal, and will never corrode. All cast iron yokes, pins, screws, gearing and clock work are avoided, there being but one valve, and one lever, and that direct acting, so that it is sure to blow the alarm when the water leaves the float. The height of water in the boiler is indicated in the glass, and the water cannot possibly leave the glass without the alarm being given. The glass gauge and alarm are each separate and complete in itself; the glass gets broken from any cause, the valves can be shut off and a perfect low water alarm still remains.

The alarm gives the engineers a gentle warning as the water approaches a dangerous state in the boiler, and if disregarded will soon alarm the whole establishment. They preserve the boiler, for with this protection the flues or rounsheet or sides of the boiler can never be injured for want of water, neither can the boiler be exploded. Every gauge is provided with a test and blow-off valve, the full size of the pipe, so that it can be tested as often as desired. The alarm gauge can be attached to any boiler already having a glass water gauge without making any additional holes in the boiler. Parties desiring further information can communicate with the agent, whose address may be found in our advertising columns.

PROFESSOR SILLIMAN has published a card in New York, with regard to the use made of his name in the complaint of the English stockholders in the Emma mining company against Ark, Stewart and others, in which he says very charge contained in that complaint, emanating from any source, imputing to me fraud, complicity or other improper act, either in connection with the examination of the Emma mine, with its sale, or with the owners hereof, is entirely without a shadow of truth."

A. V. M., HELENA, M. T.—Your question answered by mail. Owing to the large amount of growth of timber on this coast our mechanics have, in order to meet the demands, tactically placed themselves in advance of all others in the manufacturing of saw-mills and lumbering machinery. We are always pleased to answer queries concerning machinery desired in this coast, and invite mechanics to give us their views of what is wanted.

HEAVY BLAST.—They fired a blast of 80 kegs of powder, in the Union claim at Truckee Flat on Tuesday, which blew rocks and gravel out, totally demolishing the company's blacksmith shop, doing great damage to Michael Dougherty's house and barn, and killing a young colt which was in the barn. The mines are working full force.

ANVIOKE from the Quahay (Arizona) mines say the minees are paying a good profit, and will soon pay largely.

The Oregon Mining Excitement.

They are having quite an excitement in Oregon over mining matters, and people are getting quartz on the brain badly. The excitement in the southern part of the State is by no means confined to the Galice creek discoveries. There are numerous prospectors tramping the gulches and hill-sides in all directions, and bringing in specimens daily. They have not only found gold, but cinnabar also. A 12-foot deposit of cinnabar is reported on Louise creek and indications are also found on Wagner, Griffin, Sam's and Brush creeks; as also on Farmers' Flat. They have found a large ledge, almost 20 miles north of Jacksonville, which is pronounced very valuable. The principal excitement, however, is at Galice creek. The

Smith's Improved Rein Holder.

developments made there lately, particularly on the Yank, or mammoth ledge, are beginning to excite considerable interest. Nothing has been done until lately to prove the value of the mine. The ledge in question is stated to be from 100 to 210 feet wide, which if true would make it probably the largest ledge ever discovered, discounting Fansmirt altogether in this respect. It is said to assay from a trifle up to \$500 per ton; but if it will work \$15 per ton and is as wide as claimed, it ought to be a fortune for the owners. The ore contains silver principally. The Oregon Sentinel states that two mills will soon be put up. Reynolds & Co. have a 40-stamp mill on the way, and a California company have a 50-stamp mill coming. Wood and water are abundant, and a wagon road is being constructed from the stage road on the north to the ledge, about 60 miles.

At present the snow has prevented much of a rush, but the Oregon papers predict a crowd in the spring. There are various other ledges in the same range of mountains, that are now being prospected. Some 15 miles of the Yank ledge are already claimed. The main ledge has numerous veins of rich ore running through it from one to ten feet wide. In other parts of Oregon the late rains and melting snows have put water in some of the ditches and smaller creeks and the miners are beginning to work.

Oregon was credited with \$609,070 last year, as her bullion product, and if these discoveries prove half what is claimed for them she ought to quadruple the amount in 1875.

ANOTHER instance of a bankrupt estate being saved by a rise in mining values, is that of A. Delano, of Graec Valley, which was heavily encumbered at the time of his death, but it is now likely to turn out all right and leave a handsome balance. Mr. Delano was a heavy owner in a local mine, which is now yielding very rich rock.

Smith's Improved Rein Holder.

This improvement is intended to prevent the fastening of the reins to the bridle in a twisted condition; also to keep the former from falling under the horses feet when unattached to the bit, or from dropping under the tongue of the vehicle. The device is represented in our illustration secured to the harness and also separately in Fig. 2. It consists of a simple metal casting, having one pivoted roller, A, and another not pivoted but forced in close contact with the first by means of a spring, B. The rein is passed through between the rollers and thus supported.

On work harness the rein holder should be made pendent to conform to the position of the reins. On light harness it may take the place of the terret, and thus, it is claimed, be of greater service than a rein holder secured to the carriage, since it keeps the reins up in front of the animal, so that he cannot get his fore feet over them. At the same time the reins when thrown over the dashboard are less liable to get under the horses feet and tail. The inventor points out that in similar devices, which keep the reins taut, the horse is apt to put his tail

Weldon's Low Water Alarm Gauge.

over, and so pulling on the lines, to cause himself to back, thus breaking the hitching strap, a difficulty evidently obviated by the present invention. When used on backpad of harness the rein holder should be made of terret form where it is secured to pad, with rollers grooved for round reins. This device was patented by A. K. Smith, of Nebraska, Pickaway county, Ohio, who may be addressed for further information.

ESMERALDA.—A subscriber of ours writing from Lida, Esmeralda county, Nev., says: "I am compelled to complain a little of the condition of my paper on its arrival here. It would appear as though all the worthy postmasters on this side of the Rocky Mountains are thoroughly convinced that Esmeralda county, Nev., is in Mexico, and Mexico in Acapulco, and, therefore, all the letters and papers mailed for this place must first take an ocean voyage and then work its way to its destination the best it can. The result of this little arrangement is that mail matter that should reach here in six days from San Francisco is a great deal longer coming. The Press of January 9th, arrived on the 22d, and of late three sheets of the paper are chafed through now by being carried on the backs of mustangs. If the postmasters would send on mail matter by way of Austin, Nev., instead of Mexico, it would come in half the time, and the papers not be so defaced as to be unreadable. If you can do any thing to correct this nuisance you will greatly oblige this community." We give space to the above in hopes that the wife of some postmaster will cut it out and read it slowly to her husband at such times as she may want to convince him of the stupidity of postmasters in general, and her postmaster in particular. Its no use to argue with a postmaster; he must be allowed to think he is having his own way even if you are really having yours.

Bullion Product.

It is well known that the figures representing the annual bullion product of the Pacific States and Territories are always lower than the real production. Nevertheless the tables furnished by Wells, Fargo & Co. are recognized as statistics upon which to base calculations of advance or decline, as there are no others except such as are based upon estimates alone. This company, as common carriers, handle most of the bullion produced, carrying it from the mining districts to the mints, where it is coined. They have, therefore, the best opportunity of obtaining reliable data with reference to the bullion production. Still it must be remembered that the figures they give only represent what has actually passed through their hands, so that there is no danger of an over statement. But considerable dust and bullion is carried from the mines by private hands, of which Wells, Fargo & Co. know nothing. It frequently happens in this State that after a clean-up, a miner with a few thousand dollars, who is going to San Francisco, will carry his own bullion so as to save the charges of the express company. This, of course, happens elsewhere, so that the bullion product, as stated by Wells, Fargo & Co., falls actually short of the real product.

How much it falls short, is, of course, impossible to say; but 20 per cent. is usually added to the sum actually handled by Wells, Fargo & Co., for that carried by other means. There is considerable complaint from the newspapers in the Territories, especially those with comparatively small production—concerning the amounts as given by Wells, Fargo & Co. They perhaps, forget that without these statistics, which are compiled with some trouble by Wells, Fargo & Co., we should be entirely at the mercy of estimates, or would have to wait for those compiled by the United States Mining Commissioner, which are published a year or two behind time. Mr. Valentine, the General Superintendent of Wells, Fargo & Co., deserves credit instead of blame for furnishing us such as he does. Mr. Valentine considers that the allowance of 20 per cent. for "under-valuation and other conveyances" is a liberal concession. In some of the Territories, Arizona and Colorado, for instance, the statement is usually considered low. From Colorado and Utah considerable ore and base bullion is shipped, of which Wells, Fargo & Co. have no official knowledge. In Arizona considerable dust is shipped by private hands, as, in fact, is the case in all the States and Territories.

The bullion statistics give Arizona this year, a very poor showing for all the work done in 1874, and the figures are undoubtedly low. Colorado complains of injustice in this matter also, as will be seen by reference to an article in another column. In fact, the figures of all the States and Territories are small and may be taken as a minimum statement; Nevertheless they are much more reliable than mere estimates, and certainly more correct than half the statistics we take for granted on seeing them in print. The Government sets aside such a meagre appropriation for the collection of mineral statistics, that it is impossible for the Commissioner to collect them in any systematic manner. If all mine owners would send to some authorized individual an account of their work, it would be all right; but mine owners will not do it any more than people will pay taxes without compulsion. When the minees are prosperous the owners say they do not wish to parade their private affairs to the public, and are independent; and when the mines are poor the miners are still independent and even less likely to furnish information as to the result of their work. We fear that it is impossible to expect ever to have any thoroughly reliable statistics of the aggregate results of mining in the United States; but still we should not grumble at those prepared for us free of charge by a private corporation, which really had no direct interest in the matter.

CORRESPONDENCE.

The Australian Colonies.

ENTRONS PRESS:—As there appears to be every probability of a permanent line of steamers being established between San Francisco and these colonies, which will afford greater facilities for the transaction of business between the respective peoples, I have thought it might not be unacceptable to your readers to know somewhat concerning the area and population, resources and requirements of the several colonies forming the Australian group, more particularly as I have found from frequent intercourse with gentlemen from your State that gross misconceptions, both of the place and people, are commonly held by California residents.

Will you hear with me then if I make the commonplace observation that there are seven Australian colonies—five on the continent of Australia and two in the islands adjacent. Of those on the continent four only are of any consideration—the fifth, Western Australia, being separated from the rest by nearly two thousand miles, and used only as a penal station by Great Britain. The remaining four are named respectively Victoria, New South Wales, Queensland and South Australia, the order in which they are named indicating the wealth, population and importance, whilst in area Victoria is by far the smallest and South Australia by far the largest. New South Wales again is larger than Victoria and Queensland than New South Wales, a vast portion of Queensland and South Australia, being altogether unsettled. The island colonies are named respectively New Zealand and Tasmania, the first consisting of three islands of considerable size and ranking, at all events, third in importance of the whole group; whilst Tasmania is at the bottom of the list for everything except the salubrity of its climate.

With respect to area, population, trade, revenue and public debts, the following are the statistics:

Relative Condition of Australian Colonies.

	Area in sq. mi.	Population.	Imports.
Victoria.....	92,198	780,492	16,539,856
New South Wales.....	328,437	560,275	11,033,333
Queensland.....	678,600	146,690	2,835,493
South Australia.....	914,730	198,257	3,841,100
New Zealand.....	105,000	310,437	4,663,687
Tasmania.....	26,215	104,217	1,107,167

	Exports.	Revenue.	Pub. Debt.
Victoria.....	15,302,454	3,943,691	12,445,722
New South Wales.....	11,315,829	3,324,713	10,819,415
Queensland.....	3,542,513	1,120,084	4,786,850
South Australia.....	4,587,859	937,648	2,174,900
New Zealand.....	5,610,371	1,420,216	12,509,646
Tasmania.....	893,556	293,763	1,477,600

The provincial revenues of New Zealand are about \$1,500,000 in addition.

All these figures show pretty conclusively that Victoria is a long way ahead of the others in every respect, although the people of New South Wales, try hard to make themselves and others think differently. There is no doubt, however, that New South Wales, and in fact, all the Australian colonies—Tasmania only excepted—are in a sound and flourishing condition. Never during the 19 years I have been here has the look out all around seemed so promising. It is true the yield of gold has fallen off to some extent, and seems likely to fall off still farther, nevertheless, copper mines, tin mines and coal mines are being opened and worked, manufactories of various kinds are multiplying, the land is being settled upon and systematically worked, whilst the wool growers and cattle breeders are getting disgustingly rich. In addition to all this, the price of food is very low, and any man can save who will. There are some men, however, who seem to have no will about them, except it be to loaf and get drunk as much as possible.

The most important scientific event of the last month is the Transit of Venus, the nature of the observations taken of which, will be better understood by reading the accounts in the Australian papers, than by any description I could give.

Melbourne, Dec. 15, 1874.

OVER one hundred Chinamen have left Columbia since Friday week—most of them for the new quicksilver mines. After defacing the fair appearance of the "Gam," despoiling the best of her mines, robbing the country of thousands, leaving houses in the air on stilts, with unlighted holes beneath as the only relic, they depart like a lot of vultures from a carcass of dry bones, only to prey upon some other unfortunate community. However, there is one thing in their favor—they dislike to go below their noses in a mine, and this cowardice keeps many of them out of rich deposits. The ground mined up in the town can be easily slummed in and be made as good as ever. This will be done some day when a new condition of things transpires and a new population crowds the county. These mountain towns and hill-sides will come out brighter than ever.

A new ledge, with a very promising appearance, has been found on the southwest side of the ridge back of Pioche. The owners are Murphy, Jones & Co.

Quicksilver.

The third of the series of lectures given by the Professors of the University of California, at the hall in the Mechanics' Institute Building, was delivered on Saturday last, by Dr. Becker. The subject was "Quicksilver and Fuel." We present the first part of the lecture in full:

There can be no doubt that the most prominent characteristic of quicksilver is its fluidity at the ordinary temperatures of the atmosphere. This is, indeed, so striking a peculiarity that, except to a mind somewhat used to generalizing, mercury seems almost a substance apart, and not in the ordinary sense one of the metals. A moment's reflection, however, shows that there is nothing generically peculiar about quicksilver. The relation between the prevailing temperature of the surface of the globe and the melting point of the metals is an accidental and probably a temporary one. There is much less difference between the melting point of mercury and that of lead than between the temperatures at which lead and copper become fluid. The globe has certainly once had a temperature at which all these metals were permanently liquid, and a reduction of a hundred degrees more would familiarize us with a soft, ductile metal, much resembling lead, though with a tin-white color, for which the name of *quicksilver* would be a misnomer.

The Uses to Which We put Mercury

Depend to a great extent upon its fluidity under ordinary conditions—gold, for example, would be even better than mercury for barometers—were it only liquid. It is frequently a matter of great convenience to be able to bring water in contact with melted metal, and with the exception of an alloy or two, which melt just below the boiling point of water, mercury is of course the only metallic body available in such cases. I tried in my last lecture to bring into especial prominence the similarity of the action of quicksilver, in the amalgamation process, with that of other metals in a fluid state, and showed that the main difference is in the replacement of the melted slag of the furnace by a watery emulsion of the rock in the barrel or pan. A vast proportion of the mercury yearly produced is employed in amalgamation. Most of the remainder is consumed in the manufacture of vermilion paint and mercurial drugs.

Quicksilver sometimes occurs native in connection with its ores, but generally in inconsiderable quantities. It is also sometimes an ingredient of a complicated mineral called tetrahedrita, but by far the most important ore of mercury is the sulphide, called cinnabar, and identical in composition with the vermilion of commerce. The largest deposit of this ore is at Almaden, in Spain. The Almaden mine has been worked since 700 B. C., and is scarcely even well developed yet. The second largest deposit is at New Almaden, in this State; but as this far known, it does not approach the Spanish deposit in value.

Quicksilver belongs to the same general group of metals as gold and silver, and like them its affinities are weak, or in other words, its compounds are readily decomposed. The beneficence of cinnabar depends upon the fact that sulphur unites with much more strength with most other substances than it does with mercury. If cinnabar be heated with lime, the sulphur of the ore combines with it, forming sulphide and sulphate of lime, and leaving metallic mercury. If we heat cinnabar in a current of air, the mineral is also decomposed; the sulphur unites with the oxygen of the air to sulphurous acid, the unpleasant smelling gas we have met so often in these lectures, and metallic mercury is again left behind.

Perhaps you may remember that when sulphide of lead or galena is heated in a current of air, the oxygen attacks both constituents of the mineral, and we get, as here, sulphurous acid, but in place of metallic quicksilver, oxide of lead results. Gold, silver, platinum and mercury, the noble metals, are not attacked to any extent by free oxygen, and hence in the present case, metallic mercury is produced by simple roasting.

Quicksilver Possesses a Property

Which greatly simplifies the operations subsequent to its isolation in a metallic form. It is highly volatile and boils at a temperature of 675 degrees. It therefore distills off from the ore during the roasting, and only requires to be conducted through proper condensing apparatus to be liquified and obtained in a marketable shape. If gold and silver were but volatile at furnace temperatures, we could beneficiate their ores in the same way—i. e., sufficiently volatile; for, though we cannot distill these metals in any ordinary furnace, very small amounts of gold and silver do pass off as vapor when they are melted, and their volatility is consequently great enough to necessitate troublesome precautions, and to occasion loss, though it is insufficient to be turned to practical account.

Retorting quicksilver ores with lime is a method of beneficiating them now seldom practised, except for assay. When used this method differs but little from the retorting of amalgam, which I described in my last lecture. The retort is filled with a mixture of cinnabar and lime, and heated. The mercurial vapor passes out of the retort through tubes, cooled with water, and the liquid quicksilver drops from the end of the tube. The retorts are sometimes made so that they can be charged from the outside of the furnace, and thus be

kept at work continuously. A larger percentage of the metal is obtained than by the process of roasting; but the cost of apparatus, labor and extra fuel more than compensate for the gain under ordinary conditions.

The Oldest Cinnabar Roasting Furnace

Still, or until recently, in use is the Bustamante furnace. In this apparatus the ore and fuel are charged together in a short vertical shaft, and air is admitted from below and from the side. When the fuel is incandescent, the air decomposes the cinnabar and the volatile products, sulphurous acid, mercurial vapor and carbonic acid pass off through flues into two large, square chambers, where the gases are somewhat cooled. At some distance there is a second pair of chambers, and the two sets are connected by several tubes. These tubes are formed of short joints, and each joint is an earthen vessel swelling at the middle and with one end larger than the other, so that the small end of one "aludel," as these vessels are called, may be thrust into the large end of the next. The joint is made with clay. These composite tubes slope from each end toward the center, and rest on a foundation of masonry. The mercurial vapor passing through this tube is cooled down and the metal is deposited in drops, which, on account of the inclined position of the tubes, run down to the central point. A small hole in the under side of the aludel occupying that position allows the metal to escape and collect in vessels set to receive it. So much of the vapor as escapes condensation in the aludels passes into the second set of chambers, where another portion is liquified, and the remainder passes out into the air and is lost.

Besides the metallic quicksilver another product is condensed, called soot. Its composition varies, but it contains flour of mercury, i. e., quicksilver in exceedingly minute globules; undecomposed sulphur of mercury, for cinnabar is itself volatile, and, when air is not brought in contact with it, may be distilled unaltered; calomel, when there has been any salt in the ore, and soot proper, formed by the imperfect combustion of the fuel. This product is collected and worked over by hand with lye to cleanse the minute globules of the metal from impurities, whereupon a large portion of them unite to drops and are thus recovered. The remaining matter is added to the ore at the next charge.

The mixing of fuel and ore, as practiced in this furnace, has one great disadvantage. If at any time there is more fuel than there should be, too great a heat is produced, and if there are easily fusible compounds in the ore, such as silicate of iron, a glaze is produced, which in this, as in all roasting, interferes very much with the proper action of the air upon the ore.

The Aludels, too, are somewhat difficult of manipulation, and it is very hard to make the joints between them tight, and no one would now build a furnace on this plan.

The New Almaden furnace consists, in the first place, of a large square shaft, two opposite sides of which are broken through with numerous openings. This shaft is filled with lumps of ore so arranged as to leave passages through the mass, but no fuel is mixed with it. The fireplace is placed on the outside of one of the perforated walls; the flame strikes through the perforations into the ore and the gaseous products of the process pass through the opposite wall into a series of condensers. The condensers are large chambers of brick, wood, or iron, in which there are cross-walls, and these cross-walls are broken through alternately at the bottom and the top to admit of the passage of the vapor, but at the same time to compel it to take a circuitous course. This at once lengthens the distance over which it must pass, giving it time to cool and, by producing gentle eddies in the current, favors the fall of minute particles of solid or liquid matter. The floors of the chambers are curved and slope toward the outside wall, so that the metal, as it liquifies, may collect at one point in each chamber, whence it may either be allowed to run out continually through a small opening, or may be tapped when it has accumulated. As the vapor must be cooled down as far as practicable, the natural draft is very slight, and a tall chimney, generally with a small fire in it, is needed to draw in the requisite amount of air through the grate.

The working is very simple; the fire is gradually increased from the start until, after from three to four days, the mass of ore has come to a moderately bright red heat, plenty of air being admitted all the time. When this point has been reached, the distillation is considered complete, and the furnace is closed up and allowed to cool. As soon as it is cold, the exhausted ore is removed through suitable openings and the furnace is recharged.

Other Difficulties.

The necessity of allowing the furnaces I have mentioned to cool down before re-charging, involves great loss of time and fuel. The first furnace devised to allow of a continuous working was the Haehner furnace. In this the ore and fuel are charged together into a shaft, the bottom of which consists of a grate with movable bars. By removing one or more of these bars the lumps of exhausted ore can be allowed to drop from the furnace, while fresh material is added at the top. The condensation chambers are arranged as in the Almaden furnace. The continuity of the Haehner furnace is a great advantage, but not the mixing of fuel and ore. It has consequently been modified so as to resemble furnaces long in use for ores of other metals, by allowing the flame from one or more outlying

fireplaces to strike into the shaft filled with ore alone. An important advantage is gained as in the exceedingly similar Swedish roasting furnace, by placing the openings for the entrance of the flame some distance from the bottom of the shaft, and allowing the air for roasting to enter at the opening intended for withdrawing exhausted ore. In this way the air is heated by the hot worthless material, and the heat thus returned to the upper portion of the furnace.

The "Knox & Osborne" furnace of California and the latest furnace of the works at Idria Southern Austria, corresponds to this general description. The former is provided with a single fire, which draws straight across the column of ore in the shaft, and is built of heavy brick walls. The Idria furnace, of which a copy is now putting up at New Almaden, is provided with three fire-places, which draw through nearly three-quarters of the height of the column, the gases passing out through openings close to the top of the furnace. The wall area of a construction first adopted in England for iron-blast furnaces, and since applied with great success to a variety of other furnaces—comparatively thin lining of fire-brick, surrounded by an annular space filled with air, appearing admirably as a non-conductor of heat outside of which is another thin wall of brick enclosed in a shell of boiler-iron. The charging apparatus is also borrowed from blast furnace construction, and is of the kind called Pary's hell and hopper. The mouth of a circular hopper is closed by drawing up into it an upright suspended cone. When the hopper is filled the cone is lowered, and the ore enters the furnace, but its fall is broken by the presence of the cone, and it is thus necessarily distributed in all directions in the furnace. The cone is instantly raised again, and thus shot off the escape of gas.

The Condensers

Of a quicksilver roasting furnace form, of course, an exceedingly important portion of the structure, and no absolutely satisfactory construction has thus far been hit upon. Brick an exceedingly porous material, and quicksilver both filters through it and is absorbed into it by the almost irresistible force of capillary attraction. Some years ago, in piling down a old furnace at New Almaden, it was found that the metal had penetrated the foundation at the earth for over thirty feet, and down to the bed-rock. Since then the furnaces have been built on arches, and in the pillars, on which the arches rest, sheet iron plates have been placed to intercept the metal in its downward course; much metal, however, undoubtedly penetrates the outer walls of the condensers and is evaporated from the surface; for mercury evaporates more or less, at all temperatures above the freezing point of water, and the condensers, though built of a very considerable thickness, are, of course, somewhat warm on the outside. On the other hand, the thicker the condensers, the less does the vapor inside cool; and, as it must cool to condense the necessity for thick walls renders a large number of condensing chambers indispensable. It is natural, therefore, to seek some material better adapted to the work required than brick. Cast iron and wrought iron answer very well for condensers, so long as the gas is hot, but when the temperature falls below the boiling point of water, a very disagreeable action occurs. Sulphurous acid, heated with air in contact with highly porous substances, is partially converted into sulphuric acid; this condenses with the water and attacks and soon destroys the iron. Wood withstands this action tolerably well, and does not let quicksilver through like brick. It has, consequently, been much used for the later condensers of the series; but wood is a non-conductor of heat and hence, properly speaking, ill adapted to cooling apparatus. At New Almaden glass found to answer excellently, being a much better conductor of heat than wood, though not so good a one as iron, and being, of course, quite unaffected by the acid liquids. The condensers assume a great variety of forms, such as chambers of various shapes and tubes; columns of coke are also used with some success as final condensers. The draught sometimes kept up by the aid of a chimney with or without the help of a fire to give air in the stack additional buoyancy, and sometimes by a suction fan, or a "water drum," apparatus which sucks in air by means of friction of a jet of water. So far as the condensation is concerned, an artificial blast would be preferable, but the danger of blowing jets the metallic vapor through fine cracks in apparatus would be too great to admit of employment.

The Losses in Quicksilver Smelting are various and very important, though they are not all very well understood. The whole of gas passing out of the last condenser is untraced mercurial vapor. The amount of metal contained in this vapor depends on the temperature, and for low temperatures is very small per cubic foot, but its aggregate amount day is by no means inconsiderable. Another source of loss is the fine dust of mercury ponded in the gas; minute globules, so small that they fall very slowly through the air, are therefore carried away in the current gas. The rate at which a spherical body is carried through the air depends upon its specific gravity and its size, and we have, therefore, only a minute velocity of ten feet, or of one foot second. As the mercurial vapor is cooled in the condensers, the mercury is separated like mist, and the individual globules, which

SCIENTIFIC PROGRESS.

Natural Phenomena.

The store of human knowledge in the science of natural phenomena is receiving constant accessions from intelligent observers in every field of observation, whether upon land or water. Among the latest recorded cases we may instance the following which have come to hand in this locality during the last week:

On Wednesday of last week, about half past ten A. M., some topographical students who were out on the Presidio, near this city, while adjusting their instruments, suddenly heard a sharp whistling in the direction of the northwest. The sound increased, and passed overhead as if a shell or rocket, a whistle at first, increasing to a scream; then as a park of artillery rapidly rolling over a rough road, it dwindled into silence, passing to the southeast. Nothing was visible in the air. But the most curious thing about it was, that before the sound the needle pointed two and three-quarter degrees to the west of north. But, when the sound had ceased, and the students with pale faces gave their attention to their theodolite, it showed a variation of twenty-two and three-fourth degrees to the east.

A contemporary in recording the above says: "Who can explain this curious phenomenon? There is a nut for some of the members of the Philosophical Society to crack." If the facts are correctly reported a large meteor, invisible in account of the noon-day sun, must have passed over the city in a southeasterly direction. The highly metallic character of such a large body could scarcely have failed to have deflected the compass precisely as indicated. Coming from the northwest the needle would not have been deflected to the west as stated; and after its passage "overhead" it would have been as surely deflected to the east as was observed and noted by the "topographical students."

Another phenomenon, indicative of the existence of submarine volcanoes has been reported the past week by Captain McKenzie, from the South Sea Islands. While Captain McKenzie, on April 30, was sailing with his ship among these islands, about twelve miles from land, he observed a large column of water about up fully one hundred feet in the air, from this water arose a dense cloud of what appeared to be steam. The spot where this phenomena occurred is marked on the maps as shoal. As long as he was in sight of this water it continued to be sent up with equal force.

Gramme's Electric Machines.

M. Gramme has made a communication to the Paris Academy of Sciences respecting the improvements which he has made in his electric machines. The original machines ignited four inches of platinum wire three-tenths of a millimeter in diameter; the improved machines will heat to redness four times that length of the same wire, without any increase in the weight of the materials or in labor. This augmentation in the intensity of the current is principally due to the employment of the new iron plate magnets of M. Jamin. The new electro-galvanic machines have only one central magnet instead of two, and two electro-magnets instead of four in the former machines. They weigh only 177 kilograms instead of 750 kilograms. The power required to work the machines, as compared with the old, is only as 10 to 75.

They have the following advantages: They require half the space; they are three-fourths lighter; they economize three-quarters of the copper in construction; they require 30 per cent. less motive power. These improvements have been achieved by the suppression of the exciting coil, the bringing of the electro-magnet into the circuit by the current, by an improved arrangement of the copper gauze of the bars of the electro-magnets, and by a slight increase in speed. The original electric light machine fed a regulator of 900 candle burners, its weight amounted to a ton, and it occupied a space of 80 centimetres square, by one 1.20 meters in height. This machine heated itself and gave rise to sparks between the bobbins and the conductors. The new machine is composed of a frame work in cast iron, to electro-magnetic bars and a single movable central magnet, instead of six bars and three rings. It is only fifty-five centimeters square, and sixty centimeters high, and its normal power is two hundred burners.

THE VELOCITY OF LIGHT.—M. Fizeau and Cornu have been measuring the velocity of transmission of light, by experiments carried on between the Paris Observatory and Montigny. The light sent to Montigny is reflected and returns to the Observatory, the distance there and back being twenty-two thousand yards. This experiment has never hitherto been made on so large a scale, or with such precautions. Ten powerful instruments were used.

ANOTHER NEW ASTEROID.—The Smithsonian Institute has received a cable dispatch announcing the discovery, at Berlin, of a new planet, in right ascension 23°, declination 18° 16' north, of the twelfth magnitude.

Importance of Science to Industrial Operations.

The importance of the application of science to the ordinary industrial operations is becoming more and more important. The grand practical truth is now quite generally admitted that all real progress must arise from the pursuit and application of science—and of all the sciences none possess so much value as that of chemistry. Let the reader ponder the following paragraph, from a recent editorial article in one of the leading and most sterling practical journals of England. *Iron*, speaking of special education in chemistry, says of its own country:

"Chemistry is felt by those who care for science itself to be the corner stone of the natural sciences, and by those actuated by commercial considerations to be the best paying investment. In iron works, breweries, chemical works, dye works, and some other manufacturing premises, the presence of at least one chemist on the premises is now considered indispensable; so much greater is the confidence of the modern mind in scientific accuracy than in rule of thumb. This recent revolt against the 'practical man' has vastly increased the demand for skilled chemists, and even for persons possessed of a less degree of chemical knowledge. Supply has followed demand, and every smart youth now thinks a knowledge of chemistry indispensable."

THE AGE OF COAL.—INTERESTING FACTS.—Recent observations render it highly probable that vegetable matter may, under favorable conditions, be converted into coal much more rapidly than geologists are in the habit of assuming. A curious instance has been brought before the German Geological Society by Herr Hirschwald, of Berlin. In the Dorothea mine, near Clausthal—wood originally employed as timbering has become so far altered as to assume most of the characters of a true lignite or brown coal.

It appears that certain of the levels in the ancient workings of this mine are filled with refuse matter, consisting chiefly of fragments of clay-slate, more or less saturated with mine water, and containing here and there fragments of the old timbering. This wood, when in the mine, is wet and of a leathery consistency, but on exposure to the air it rapidly hardens to a solid substance, having most, if not all, the characters of a true lignite. It breaks with a well-marked conchoidal fracture, and the parts which are most altered present the black lustrous appearance characteristic of the German "pitch-coals." At the same time, chemical examination of the altered wood shows that it stands actually nearer to true coal than do some of the younger tertiary lignites. This instance seems therefore, to prove that pine wood, when placed under highly favorable conditions, may be converted into a genuine lignite within a period which, from what we know of the history of mining in the Hartz, cannot have extended beyond four centuries.—*Athenaeum* London.

PETROLEUM IN NORTH GERMANY.—The discovery of petroleum springs on the Luneburg Heaths in North Germany is an interesting scientific fact, and one which promises to convert this once barren and apparently unavailing tract into what might by comparison be designated as an El Dorado. Borings were made at Oberg, by Hanoverian and French surveyors as early as 1863, but then the measures taken failed to confirm the opinion which had been previously advanced of the presence of oil. Since 1872 petroleum has been obtained without intermission, although the process adopted for its extraction has consisted in little more than a mere washing of the sand, through which the oil was suffered to run into vessels prepared for its reception. A remarkable fact is also reported in connection with this, to the effect that this petroleum is remarkably pure and inodorous! It may not be out of place in this connection to refer to the commercial fact that manufactured petroleum constitutes, at this time, the most important item of our manufactured exports—its annual value is about \$41,000,000, of which Germany receives about \$11,500,000.

MUD BANKS IN THE OCEAN.—A curious phenomenon frequently met with in the Indian Ocean, the real cause of which has not yet been ascertained, is the existence of Malabar, and in certain spots along the Coromandel coast, of vast mud-banks, and of tracts of mud suspended in the sea, wherein many kinds of fish find abundance of food, immunity from much disturbance in the surrounding element, and a place in which to breed. The exact cause of the existence of these large tracts of the sea wherein mud remains in solution is still a mystery, but at any rate the tracts are so smooth, that, even during the height of the southwest monsoon, vessels can run for shelter into their midst, and once there are as safe as when inside a breakwater.

AGE OF THE AUSTRALIAN GOLD DRIFT.—Among some fossils recently described by Professor M'Coy, of Melbourne, is an extinct wombat from the gold drifts of Victoria. This fossil, called *Phascodomys plicatus*, is of much interest, as having enabled Professor M'Coy to show that the auriferous deposits whence it is derived, instead of being merely alluvial, should be referred to the more ancient pliocene period, thus corresponding in age with the gold drifts of the Urals.

MECHANICAL PROGRESS.

Explosives as a Source of Power.

In considering the motive power of the future, it is impossible not to reflect upon the possible utilization for this purpose of explosive agents, such as gunpowder, the picrates, etc. They all may be considered as magazines of immense power, incomparably greater than the power stored up in any of the ordinary combustibles, such as coal or petroleum. In this view of the case, the following extract from a paper by M. Champion, an excellent authority upon the subject, becomes interesting:

"It is estimated that the explosive power of nitro-glycerine is equal to ten times that of gunpowder; 1.1 pounds would lift from the ground and project a weight of 160,000 kilograms. The heat evolved in the reaction is about 1,282,000 calories for each kilogram. This same kilogram of nitro-glycerine, exploding in a closed space having a volume of one liter, develops a theoretical pressure of 243,000 atmospheres, a temperature of 93,400 degrees, and a quantity of heat equal to 19,700,000 calories.

"One liter of nitro-glycerine weighs 1.6 kilograms. In exploding in a space completely filled with it, as it happens in a blast-hole in mining operations, or when operating under water, this substance develops a pressure of 470,000 atmospheres; a pressure eight or ten times that produced by the same volume of gunpowder.

"The heat thus developed being 38,000,000 calories, the mechanical labor produced, which is the equivalent of this, rises to the enormous number of more than sixteen thousand million kilogram-meters, a value five times that of the maximum value of gunpowder."

"A kilogram of coal contains about 8,000 calories," says the *Revue Industrielle*, "each calory being equivalent, theoretically, to 120 kilogram-meters. Hence, the maximum mechanical work of 1.6 kilograms of coal would be 5,476,000 kilogram meters; a quantity 3,000 times less than is produced with the same weight of nitro-glycerine.

"Is not the imagination of the most enthusiastic inventor," it continues, "staggered in presence of these enormous numbers? What an answer, too, do these figures furnish to the pessimists who see in the exhaustion of our coal mines the extinction of the industries of the future. In a single liter of nitro-glycerine there is stored up the enormous labor of 5,500 horse-powers acting continuously for ten hours."

AMERICAN MACHINERY ABROAD.—There is a steady growing export demand for American machinery. The Burleigh Rock Drill company, of Fitchburg, Massachusetts, have just shipped three large air compressors to furnish motive power for running drills and pumps in the silver mines among the mountains of Peru and Chili. Some American locomotives and some machinery have been sent thither previously, and chiefly to Oslao and Valparaiso. Locomotives and machinery have gone to Rio Janeiro; axes and sawmills up the Amazon, sugar mills and evaporators to Buenos Ayres; gass fixtures and chandeliers to St. Petersburg; passenger railway cars and saws to England and the continent; arms to the same destination; scales and sewing machines everywhere. And, thus, step following step, a beginning is even now made in some departments sufficient to show that foreign appreciation of our manufactures is great enough to promise them a market when the condition of labor and living are such that we can fill it.

IRON WIRE—SINOULAR PHENOMENON.—In drawing certain numbers of iron wire, it often becomes necessary, in order to continue the use of the drawing bench, to anneal the iron. This is done in a hermetically closed receptacle, so as to avoid, as much as possible, the oxidation of the metal. In spite of this precaution, however, the latter becomes covered with an ochraceous film, which it is necessary to remove by an acidulated bath. It frequently happens, however, that subsequent to this process the metal becomes so brittle as to render its further drawing impossible. M. Serot, engineer of the *Société des Forges de la Frenche Compté*, has examined into this phenomenon, and finds that the iron becomes charged with a condensed gas. On breaking the wire under water in a test tube, inflammable bubbles were generated which detonated in the air. The exact nature of the gas has not yet been decided, nor that of its direct action upon the metal; but it is believed to be either hydrogen or carbonic oxide.

AN IMPROVED POWDER.—The *Baltic Gazette* says that the German Government has just adopted a new kind of prismatic powder for its heavy guns, which is far superior to that used in England and Russia. The powder hitherto used by the Germans was similar to the Russian, and was proved to be more effective than the English 8-inch Woolwich gun and a Prussian 72-pounder, on the artillery shooting ground at Tegel. The new powder consists of hexagonal prisms like the old, but the prisms are pierced with one hole, only instead of seven, and the specific gravity of the powder is raised from 1.65 to 1.68. According to the *Baltic Gazette* the results produced by this improved powder are extraordinary, and a Prussian 28-centimetre gun loaded with it is equal to an English 11-inch gun with the ordinary powder.

SMOKELESS FURNACES.—M. Foncault, in a report to the Industrial Society of Rheims, combats the idea that the smokelessness of a fire can effect a notable saving in the amount of fuel burnt. He alleges also, on the other hand that a considerable loss of economy is produced by smoke consuming apparatus. He brings in support of his opinion the long series of observations made by the Industrial Society of Mulhouse, which have proved that with the ordinary boiler furnaces it is only necessary to consume from 125 to 150 cubic feet of air for each pound of coal, while furnaces for the most part pass twice that quantity. If the draught be reduced in quantity, much smoke is evolved, but the products of combustion, circulating more slowly, part with their heat more readily to the boiler flues. It is further proved that the best means of reducing the loss of heat by the chimney is by the use of feed heaters in the flue, so as finally to reduce to 200 deg. the products of combustion, which are often discharged as hot as 400 deg. Feed water heaters will set will produce an economy of from 11 to 20 per cent., with a reduced draught. The conclusion is that furnaces with large area and suitable feed heaters are the most economical in all respects. But in order to obtain the best results, much care is needed in stoking. A little at a time and often should the coal be spread over the front of the fire, and the bright coal pushed back to the bridge. At the same time the least possible quantity of cold air should be admitted.

LITHIUM GLASS.—The following is an abstract of a paper on lithium glass, read before the American Association for the Advancement of Science, by Mr. Charles B. Dudley: The alkaline nature of lithium was evident, from the very discovery of the element. It occurred to the author by the experiment of making a glass with lithium, and of determining its properties. It was thought best to make the experiment with the most fusible materials; and the attempt was made to obtain a silicate of lead and lithium. The silica was obtained from common quartz crystals, pulverized and treated with hydrochloric acid. The lead was commercial red lead. The lithium was a carbonate precipitated by carbonate of ammonia from crude chloride. Eight fusions were made, and no attempt was made to fuse more than twenty-five grains at once. There were many difficulties in the operation of the experiment, as from the presence of iron, the small quantity of materials employed, and the lack of conveniences in the laboratory. But three pieces of glass were obtained large enough to work with. The glass is clear, quite hard, somewhat tinged with green, probably on account of the presence of iron. Its specific gravity is from 3.3 to 3.6; its index of refraction is 1.60; its dispersive power was not satisfactorily determined.

The reported (almost) malleable glass, to which we have already made frequent reference, seems to be an undoubted reality. We find the following further reference to this important discovery in a late number of the *Revue Industrielle*. The inventor of this important improvement in glass manufacture, M. de la Batie, is about to erect a factory for the production of articles of this new glass. From his patents it appears that his process consists in smelting the glass while yet in a pasty state, at the time of its fusion and in the furnaces where it is made. This annealing is effected in a liquid and under special conditions. This operation, while it does not render the glass absolutely malleable, increases its resisting power about forty times. We have seen an ordinary pane of window glass thus annealed, upon which was allowed to fall from a height of six feet a five franc piece, without causing the least damage. The importance of this discovery in all branches of glass manufacture cannot fail to be very great. The new glass works of M. de la Batie will be established at Poat-d'Ain. A company has been formed with a capital of 250,000 francs for the purpose of putting the invention into practical operation.

NEW INVENTION.—In the lower Riverside mill, Wheeling, where the iron is heated and rolled for nail plate, a valuable patent gotten up by Col. Orville C. Dewey, one of the proprietors, is in use. The improvement consists of an arrangement at the rolls whereby much labor is saved, and a decided improvement made in iron. When the plate is shoved under the rolls, a friction wheel catches it, and without requiring extra skilled labor on the part of the catcher or "shove-under," it is drawn smoothly through the rolls and comes out on a long, narrow table, from which rods slant to the lower rolls, and down which the plate easily slides. It then passes through the lower rolls and comes out on the other side on a table which turns on a pivot, and which raises it to the upper rolls, and so on to the finishing press. The nail plate made there is fifteen inches wide, which is the second widest in the United States, and shows by reason of these improvements, a polish of smoothness of edge of admirable quality. Besides the improvement on the iron we are reliably informed that the firm have effected a saving by their use of ten dollars a day, which speaks for itself of the value of the invention.—*American Working People*.

Rubber Paint.

The Pacific Rubber Paint Company, which was organized in this city a few months ago is now in running order, and the factory at 209 Sacramento street is turning out large quantities of this peculiar paint. This article is the result of investigations to produce a perfectly water-proof paint, which was accomplished by forming a chemical combination of rubber with oil paints which when applied becomes elastic enough not to crack, and has a gloss which looks like varnished work. This paint was used as long ago as 1856 in the United States. In 1870 Mr. Eaton, of San Jose, sent to Cleveland, Ohio, for some of this paint for his residence, which was the first used on the Pacific coast. His experiment gave such satisfaction that others sent for it until over 10,000 gallons of this paint was ordered for San Jose. This demand led to the purchase of the patents for the coast by the Pacific Company, who are now manufacturing pure whites and all colors in large quantities.

The particular points of superiority claimed by the company are as follows: economy, as any described surface can be covered 20 per cent. less than any other paint; durability, as changes of climate or weather does not affect it, while its greater body forms a coat so adhesive and elastic as to prevent cracking, chalking or peeling. It retains its color and gloss, and flows from the brush freely. It may be used for all kinds of painting, and especially for fine inside work, and will work well on iron, stone, wood, brick or plaster. It is claimed that no paint made will resist water equal to it, making it excellent for vessels, boats or roofs, and its peculiar character makes it retain its color throughout.

No special directions are necessary to enable any one to apply this paint; except that the first coat should be thoroughly dry before others are added. One gallon of it covers 35 square yards with one coat; 25 square yards, two coats; or 18 square yards, three coats. The same dryers are used as in other paints if found necessary. This paint is furnished mixed ready for use in all colors, comprising any number of different shades. It can be put on by any one. It is put up for shipment in cans of 1/4, 1, 2, 5, 10, 20 or 40 gallons; also in 5 gallon wooden pails and barrels. This paint can be bought as cheap as agents as at the factory. Messrs. Healy & De Forest, the principal proprietors, are introducing the product largely in this city and the interior, and already a number of buildings in San Francisco are being painted with it.

Mining Stocks.

The Mining Stock Market continues in a depressed condition, the volume of business being small and prices low. The market was up a little on Monday and Tuesday, but on Wednesday and Thursday it was "off" again. It is hardly possible that prices will continue where they are for any length of time, as some of the large operators hold more stock than they care about carrying. The general supposition is that this market has touched bottom, but, of course, no one can tell about this. It is not likely, however, to remain where it is for any length of time, any more than it was to remain high during the late excitement. News from the bonanza mines continues favorable and there seems to be no diminution of confidence in them, although the prices are much lower than for the past few weeks. Ophir goes up and down as usual and seems to lead the market. Some few descriptions went up a little this week independently of the downward tendency. Small operators are waiting to see what the market is to do, and large ones are probably laying the wires for a new deal. The late break swamped some of those even on the inside as well as many on

Thomas, late of Nashville, Tenn., a practical orker in slate, has located two ledges, in company with gentlemen of capital, which promise rich rewards. One of these ledges is situated at the south end of Chili Bar bridge, about 10 miles north from this city, and has been fully opened and tested, and proves to be first class. Some eight or ten men have been employed upon it for some time. We were shown samples of it on Tuesday that were very fine. One lot that would square about 8x10 inches, consisting of twelve sheets, were placed together as they were before splitting, were just inch in thickness, being one-twelfth of an inch the sheet, and each sheet was nearly as even and perfect as a pane of glass. Another lot, but larger, were equally perfect, though all were in rough.

YO COUNTY.

FROM COSO.—*Inyo Independent*, Jan. 30: *News*. Colby, Jewett and Brundage bring favorable news from New Coso. Several hundred men are on the ground and new discoveries are constantly being made. About two miles from the first locations some leads of bling ore have been found similar to those of Mammoth. The specimens shown by Mr. Brundage look quite as well as any ore we have seen from that place. Those familiar with the ores of the celebrated Union mine at Cerro Gordo say it is impossible to distinguish it from ore of that mine. The formation in which this mine is found is precisely similar, it is more favorably situated for work and is larger. The measurements of the U. S. Deputy Mineral Surveyor give it a width of 196 ft. A cut or tunnel is now being run across with a view to better ascertain the solidity and continuity of the vein and character of the ore.

CERRO GORDO.—There is not much doing in the way of mining. Mr. Hamilton, of the Inshy Company, with Thos. Pasmore, came up in the storm to pay Mr. Crapo for the Inshy Tunnel and some seven or eight other things on Buena Vista Hill, the titles of which could seem to have been involved in a dispute. The Potosi Tunnel is still progressing slowly. PANAMINT.—*Cor. White Pine News*: Jones & Stewart are putting up concentrating works, which will reduce their shipping ores from ten tons to one, and the concentrated metal will weigh as high as one dollar per pound, or \$2,000 per ton. Their present shipping ore, assorted, weighs \$500, consequently the concentrated concentrates will certainly reach \$4,000 per ton. There are a great number of mines here showing prospectively as well as the best, (always excepting the Jacob's Wonder), owned by parties here and in San Francisco. I look for some New York capital to be invested here as soon as Jones & Co. prove the country a success.

MINING CONTRACTS.—*Panamint News*, Jan. 30: Several contracts have been entered into by different parties on the Stewart's Wonder, one of the series of the Wonder Consolidated mines lately put upon the San Francisco Stock board. Cullen & Co. have contracts Nos. 1 and 2, and began work on the 21st of January. They employ eight men. In the upper tunnel (No. 1) they have run a distance of forty feet, are in good ore, the vein being the 10th of the tunnel and looking well. Four men are employed in this tunnel. In the middle tunnel (No. 2) four men are employed, but they have run only twenty-two feet, the rock being much harder than in No. 1. Contract No. 3 is taken by Peak & Connelly, and they are at work in the lower tunnel of the Wonder employing fifteen men. We understand a number of other contracts have been entered into by other parties on the Company's mines.

LAKE COUNTY.

NEW DISCOVERY.—*Lake County Bee*, Feb. 4: M. Davis and D. W. Lilly have discovered a new mine in Mysterious Valley, near the boundary line between Lake and Napa counties. In assay of the rock shows 26 per cent. copper, 10 per cent. gold, and 12 per cent. silver. They are taken up claims on the lode.

MENDOCINO COUNTY.

POTTER VALLEY MINES.—*Mendocino Dispatch*, Feb. 6: The mining excitement in Potter Valley is running high. They have found gold, silver, and may be, quicksilver. It is said there is not a foot of the hills surrounding the valley north, east, west, or south—but what has been staked off for a mining claim.

NEVADA COUNTY.

MANZANITA MINE.—*Transcript*, February 6: We made a visit to the Manzanita mine yesterday, and found everything progressing nicely. Any one desiring to see the bed of an ancient river can do so by visiting the Manzanita. There is over 600 feet of the channel now opened out and ready for work. A hundred feet of this channel used to yield \$50,000. It is thought the ground at present is as rich as it was in early days; but the Superintendent, to be within bounds, estimates 100 feet will yield \$30,000. At that rate—and there is no doubt that it will be greater—the ground now uncovered will pan out \$200,000. On the south end of the mine there are two pipes running, and over a thousand inches of water used. On the north end workmen are engaged in drifting. It is intended to drift through the gap east of the Sugar Loaf hill, instead of washing the whole surface. In these drifts the gravel is very rich. The gravel taken out in running one foot will yield \$50. Over a thousand dollars was taken out in going ahead ten feet. The tunnel and drifts are now in about 160 feet. The Manzanita mine is without doubt to-day the best gravel mine in the country. It is just being opened and beginning now to show what it is,

and it is also proving what others are most interested in—which way the channel runs.

NEW YORK HILL MINE.—We believe the late A. Delano owned 800 out of 1,000 shares in the New York Hill mine. The estate was badly involved, but there is no doubt now but the mine will bring everything out right. We hear it is the intention of the executors to put enough stock on the market to pay off the indebtedness. It is sending out the richest rock ever taken out in the district, and there seems to be any quantity of it.

MINING SITUATION.—*Grass Valley Union*: The mining situation of Grass Valley district, is magnificently improving. The prospectors are out and are busy, and general success will stimulate them to a continuance of enterprise throughout the coming summer. The older mines are generally doing well.

The Idaho is opening on the 8th level in good ore and a large ledge.

New York mine continues to have splendid ore. The ledge is from two and a half to three ft in thickness.

In the Omaha mine the pumps were started up on Thursday last, and in about two weeks the mine will be clear out of water.

The Pittsburg is still sending out rich ore. The best judges estimate that the ore will pay not less than \$100 to the ton by mill process. The owners are now preparing to put up steam hoisting and pumping machinery.

The Empire has greatly improved. The yield last month was about \$22,000 in gold, which gives a profit to the owners.

Machinery for hoisting and pumping purposes is being put up by the Orleans company. The machinery is heavy enough to sink more than a thousand feet.

RICH GRAVEL.—We understand the Nebraska has struck rich dirt. The mine is on the north side and adjoins the Manzanita claim. The Manzanita is on the ancient river channel. The owners are now following that channel through the gap east of the Sugar Loaf. Very rich dirt has been found in the drifts during the past two months. The Nebraska Company has been trying to get on the same lead, and we believe have now accomplished it. The gravel found will pay twelve dollars to the ton.

THE MINES.—There is plenty of water for mining purposes just now, and the weather is favorable to mining. We understand that all the mines on the ridge are running and doing well. The same is the case about here, in Little York Township, and other places we hear of. Thus far the usual amount of gold has not been taken out, and unless more rains come between now and Spring, the season's yield will be much less than usual. Quartz mines are all doing well, for what is unfavorable to the hydraulic claims is the contrary with them. There is work going on in nearly all of them, and the proceeds are generally satisfactory. Prospecting is going on in different parts of the county, and some good things have been struck. Much more of the kind will be going on when the weather becomes settled. We are ready and anxious to chronicle any rich discoveries.

PLACER COUNTY.

\$6.75 CHINK.—*Placer Herald*, Feb. 6: While Road Master Burke was engaged in repairing the damage done to the bridge on Grass Valley street, this last week, he found, while digging the dirt from the bents, a lump of the root of evil, worth \$6.75. Who says the dirt in our streets is not mixed with gold?

SALE OF MINING GROUND.—We understand that J. B. Hobson, who owns a fine farm about three miles northeast of Auburn, has sold a gravel mound on his place, to some San Francisco parties for about \$5,000. The parties have bought the mound for its mineral value, and intend to mine it by the hydraulic process, as soon as they can dig ditches, build flumes, etc., to carry water to the ground. This mound has been prospected in years gone by, and is known to be rich, and would doubtless have been mined out long ago, only for the great expense of getting water. The ground lies high and dry, and water has been the obstacle; but as in this case, as in many others, this obstacle will disappear before the power of capital. The cost of the ground is but a small fraction of what the cost to bring in water will be; but the purchasers seem satisfied that the richness of the ground will fully warrant them in making all necessary outlays for its successful working.

IOWA HILL.—*Cor. Placer Argus*, February 6: Already the benefits of the canal are to be seen. Barwell, Fuller & Co., the Enterprise Co., S. R. Kidder, and the Morning Star Co. have all been working, and are apparently well satisfied with the result of their work. The Morning Star claim is undoubtedly the star claim of Iowa Hill. It has all of the modern improvements, and is fixed up in a style second to none in the State. It has a pressure of 500 feet, which forces 1,000 inches of water through a five inch nozzle. The sound of this powerful stream as it strikes the bank resembles the rumbling of distant thunder, and it crushes the cemented gravel apparently as easy as if it was ordinary dirt. The main flume across the cañon, belonging to this company, commenced settling the night before last, when it became blocked with dirt. The water ran over the sides, undermining the flume almost its entire length, and precipitating it into the cañon below. This will delay the company about a week, and put them to considerable expense. We felt two shocks of an earthquake in this vicinity between 3 and 4 a. m., on the 24th of the present month; the vibrations were from south to north. The shock cracked the day of the

Iowa Hill Canal Company's reservoir at Fish and Brown's ranch, and the water trunk was crushed in the same night, so badly that they cannot get no water out of their reservoir except by digging a ditch through the upper portion of the dam, and lowering the reservoir by degrees. This makes it bad for the canal company and the miners. Mrs. Hill has commenced suit against the canal company for damages (the amount I have not learned), claiming that the reservoir obstructs her water rights in Shirt-Tail Cañon. The suit will not only be of local interest, but it will attract the attention of miners throughout the State. Should Mrs. Hill get judgment against the company for damages, the ground that has lately been located by J. H. Neff & Co., for the retaining of surplus water, will have to be abandoned, and all similar enterprises will have to come to a standstill.

PLUMAS COUNTY.

ITEMS.—*Plumas National*, Jan. 30: The East Branch Ditch Company came out lucky, the flood having damaged them but little.

Tom. Jolly & Co. lost part of their flume in Willow Creek by the high water.

The Baker mine, at Cherokee, is producing some good rock. Greig is at work on the Kettle ledge at Round valley.

The Indian Valley company, at Greenville, have suspended operations for the present.

The Taylor Brothers struck a vein of quartz, about eighteen inches wide, directly back of their house at Crescent, which is very rich in free gold. The specimens, it is said, show splendidly.

SISKIYOU COUNTY.

MINING ON THE KLAMATH.—From Supervisor Pickens we learn that there will probably be a great deal more mining done the coming season at Oak Bar and between there and the mouth of Horse Creek, than there has been any season yet. Quite a number of claims have been taken up and prospected enough to justify their owners in going ahead and opening them. The stretch of river from the mouth of Horse creek to the mouth of Scott river, along which several claims were opened in the summer of 1873, has been abandoned entirely. The claims taken up and opened that season, did not pay.

SONOMA COUNTY.

OUR MINING INTERESTS.—*Sonoma Democrat* Feb. 6: There is an activity beyond expectation in developing the mines in this county. Inyo district, within a few miles of Healdsburg, of which a notice appears elsewhere, is proving very rich. In Pine Flat important works are in progress. Near Cloverdale and at Gnerneville there are new discoveries and work is being vigorously prosecuted on old locations.

THE STAR MINE.—We met on Tuesday, Samuel Foster, President of the Star quicksilver mining company, Inyo district. The owners of this promising mine organized the company in December last, purchasing afterwards an adjoining claim, which gives them 3,000 feet upon the ledge next adjoining the Chepman mine. Capt. in Eastman, the Superintendent, is now working two shifts of men in a tunnel on the ledge. We were shown by Mr. Foster, rock of excellent promise from this tunnel. A quantity of boulders and float, carrying ore in paying quantity, has been broken and is now on the dump. There is no difficulty in the matter of titles in Inyo district, a fact which adds greatly to the value of its mines.

TUOLUMNE COUNTY.

THE MINE.—*Union Democrat* February 6: Reports from the Bonita and other mines in that locality of the North Fork of the Tuolumne river continue to be favorable. The prospect is that large and continuous ledges of gold bearing ore of sufficient richness to pay a handsome profit will be developed. One of the same character has been found in several claims which goes to show there is one large lead of a very valuable character running through that region. Our best mining men think very highly of the prospect and predict that the district will attract much attention the coming season. The effect of proper development is the cause, in a measure, for bringing these mines to notice. If the same course was pursued on other leads in the county it is not unreasonable to presume similar results would be obtained, and our mining interests given a status to which they should be entitled.

We understand the "Tom Evans" mine is about to change hands as negotiations are pending for its sale. Our opinion is that when this property passes out of his hands Mr. Evans will have "let a valuable bird go," and the idea, no doubt, striking him in the same place, may account, in a measure, for his indifference as to sale.

Nevada.

WASHOE DISTRICT.

OPHIA.—*Virginia Enterprise*, February 6: The usual quality and quantity of ore is being extracted from the stopes on the 1465, 1366 and 1300-ft levels and the mills are all in full operation. The cross-cut going east near the California line, on the 1366-ft level is passing through alternate strata of porphyry and very rich ore. This appears to be the west side of an ore body lying a considerable distance east of where any ore has yet been found in the mine.

CALIFORNIA.—The work of cross-cutting in No. 2 on the 1500-ft level is progressing slowly, as the rock passed through is very hard blasting and will take some time to reach the ore body. Cross-cut No. 3 on this level is now in the ore vein, which looks very flattering and is of high

grade. Cross-cut No. 1 from the southern boundary still continues in high grade ore. The same can be said of the north drift on the 1550-ft level, which is now in the vein over 80 feet. Cross-cut No. 1 on the 1400-ft level has got into the east portion of the vein. The face of the drift is in splendid ore. The vein is firm, hard and well-defined, and indications are very flattering. All of the various drifts of development are looking well.

CONS. VIRGINIA.—Notwithstanding the depression in the market, the "Pet of the Comstock" continues to hoist her 400 tons of ore daily, with assays of such richness as to surprise the world, and producing in bullion for the month just ending over \$1,000,000. The work of sinking the double winze is progressing as fast as circumstances will permit. Cross-cut No. 1 on the 1000-ft level is now in nearly 110 ft and still in ore of great value. The ore breasts on all the levels continue to improve, and everything about the mine runs smoothly. The new mill works well, crushing about 230 tons daily. The joint C. and C. shaft has now attained a depth of nearly 160 ft, and is being substantially timbered.

BECKER.—Very fair progress is being made at sinking the main incline, notwithstanding the hard rock in the present bottom. The drift east on the 1500-ft level is still in the west country rock. The winzes on the 1400-ft level are still in ore. The new air shaft will be finished to the 850 ft level next week. They have also begun raising on the shaft at the 1000-ft level. The work is being pushed as rapidly as possible. The daily yield of the mine is 500 tons of ore.

DAYTON.—Sinking the main shaft, three compartments, is progressing at the rate of two ft per day. The south drift, near the Kossuth line, is still going ahead in ore, but it is of a grade too low to pay for milling. This drift is being advanced at the rate of four ft per day. The mill is running as usual on the reserve of ore hauled to it before the storms had rendered the roads impassable.

LADY BYRON.—The main west drift from the new shaft is fast approaching to the old works, as also are its two branches. The distance to the old works is now about 60 ft. At the 80-ft level some good ore has been found in cross-cutting west from the main south drift. This ore is of the same character as that mined from the open cut on the surface and will mill \$30 to \$35 per ton.

HALE & NORCROSS.—The west drift on the 2100-ft level has been extended several ft and is now in nearly 150 ft, passing through low grade quartz. The south drift on this level is passing through nearly the same material as that found in the west drift. A fair quantity of ore is being found on the 11th station.

CALENORIA.—The working station at the 1076-ft level is making good progress and is now in a distance of 80 ft, all the way in vein material. The two-compartment ore and waste chute started from this level is up 30 ft and is being pushed upward to the point where it will intersect the incline.

OVERMAN.—The main drift at the 1100-ft level is being pushed west for the vein as rapidly as possible. The winze to connect with this drift is making good progress.

JULIA.—Promising bunches of quartz are still being cut in the main south drift on the 1000-ft level.

SENATOR.—Are drifting south on the 400-ft level in quartz of a favorable character, with some water coming in at the face of the drift.

PHIL. SHERIDAN.—Main west drift going ahead, and a winze is being sunk below it to develop the good ore streak already met with.

WOODVILLE.—There has been a considerable improvement in the north drift on the 300-foot level. The ore body has now attained a width of five feet. Sufficient ore is being extracted to keep the mill steadily employed.

JUSTICE.—It is expected that good bodies of ore will be found when cross-cutting shall have been commenced.

UNION CONSOLIDATED.—The crosscut east from the main north drift is steadily advanced in favorable material.

MEXICAN.—The face of the north drift on the 1465-ft level is still in ore from which assays of from \$40 to \$50 are obtained. The indications are that a body of ore will be reached by this drift at no distant day.

COLUMBIA.—Are putting up their hoisting works and will have their engine running about the last of next week.

GOULD AND CURRY.—Good progress is being made in the work of raising the two unfinished compartments from the eighth to the tenth stations. The drift south from the double winze has been extended several feet, and is now in 70 feet.

IOWA.—The main shaft is down 208 ft., which is as deep as it will be sunk until hoisting machinery is obtained. The required machinery has been ordered and is now ready to be shipped.

BEST AND BELCHER.—The drift on the 1,700-ft level is being pushed forward as fast as possible, and it is expected to soon connect with a drift on the same level with the Gould and Curry, when better ventilation can be had and the work of development commenced in earnest. The material passed through is still clay, porphyry, and quartz of a low grade.

CHOLLAR-POTOSI.—Nothing is now being done in the ore-producing sections, as the roads are in such a condition that no hauling can be done. The drift south on the 1,100-ft level is being advanced in hard porphyry.

YELLOW JACKET.—The main incline is down 190 ft. below the 1,740-ft level, at which point some water is encountered.

Continued from Page 98.

are too small to fall rapidly and which do not collide and aggregate with others, are to a great extent carried off as a dust. Nothing is more difficult than to filter very fine dust effectually on a large scale from a current of gas, as has been proved over and over again in the attempts made to catch the fume from silver-smelting furnaces. How much such fume is formed in quicksilver smelting must depend on various circumstances, but the formation of soot in the condensers is sure to be accompanied by a loss in this way, for the metal which is separated out at the same time as the soot will, to some extent, be coated by non-metallic impurities and rendered incapable of running together into larger drops.

The metallic mercury obtained from the condensers rarely needs any refining. Dirt mixed with it is readily extracted by filtering through cloth or leather, and it is then simply weighed out and bottled up in flasks ready for market.

The metallurgy of quicksilver is thus, as you perceive, comparatively simple, consisting essentially of but a single and by no means complicated process. The working of quicksilver ores is unquestionably susceptible of great improvements, but it is only lately that a sufficient number of cinnabar mines have been known to give employment to more than an exceedingly small number of technologists. In the future emulation and competition will probably produce rapid advances.

I shall finish the hour with a few remarks on Fuel.

Fuel is of enormous importance in metallurgy. In other branches there is, of course, a choice in fuel, but principally with reference to its heating power; while in metallurgy its chemical composition, its purity, its specific gravity, the firmness of its texture, are all matters of the greatest weight. Some fuels are used as they are found in nature, such as wood, peat, brown coal or lignite, soft coal, anthracite and petroleum. Others are artificially prepared, such as charcoal, coke and gas. All these species of fuel are originally derived from vegetable fiber, except such petroleum as has arisen from the decomposition of animal matter, and are, consequently, composed of the same constituents as wood fiber, though the proportion of those constituents depend on the conditions to which the material has been exposed. Wood fiber consists of carbon, hydrogen and oxygen. One-half the fiber by weight is carbon and the remainder consists of oxygen and hydrogen in the same proportions in which they exist in water, which, of course, is the oxide of hydrogen. When wood fiber is heated without the access of air these relations are altered; a portion of the hydrogen and oxygen unite, forming water; the remainder of each forms compounds with a small part of the carbon, and, if the process is carried far enough, almost perfectly pure carbon or charcoal is left behind. When wood fiber is buried in wet ground, changes exceedingly similar take place, though vastly more slowly, the oxygen and hydrogen leaving the carbon, but at different rates, the oxygen going much faster. This appears to be because the compounds of oxygen and carbon are either gaseous or soluble in water, while the greater proportion of those of carbon and hydrogen are tarry substances, neither volatile at the ordinary temperatures nor soluble. Nevertheless, in time the carbon is left almost pure. It does not, indeed, resemble charcoal in appearance as closely as in chemical composition, for ages of pressure, during its formation, have compacted it into a very dense mass, which we call hard coal or anthracite. Between the wood fiber and anthracite in age and in chemical composition come the other mineral fuels—peat, lignite and soft coal.

Heating Power of Fuel.

The heating power of fuel is of two kinds, quantitative and qualitative. The quantitative heating power of a fuel may be measured by the weight of water which the combustion of one pound will raise to the boiling point. The qualitative heating power is the temperature which it will give when burning. Thus we might not be able to melt copper with a certain kind of fuel, no matter how much of it we burned, though the quantity of heat would depend only on the amount of it consumed, while another fuel would melt far more infusible substances. The quantity and the quality of heat stand in very close relation to one another in the following way: The heat produced by combustion is imparted directly to the products of combustion, and these products must have the temperature of the burning body. It must, for example, be just as hot on one-hundredth of an inch above the point of a flame as at the point of the flame itself. Now, when gaseous or other bodies are heated, the heat is used up in two distinct ways; physical changes, especially expansion, take place, and a portion of the heat is used up in producing these effects, while the remainder shows itself as sensible heat or temperature. Different bodies require very different quantities of heat to produce these changes, and of all bodies, except hydrogen, water uses up most heat in rising from one temperature to another. But the products of the combustion of wood fiber and the substances derived from it are carbonic acid and water, the former being the result of the union of the carbon of the fiber with the oxygen of the air, and the latter of the union of the hydrogen with the oxygen, either of the air, or of the fuel itself, when the latter contains a sufficient quantity. Hence two fuels with equal quantitative heating powers, one of which produced a larger and the other a smaller amount of water in burning, would give very different qualitative heating effects

or maximum temperatures; that which produced the least water giving the highest degree of heat. The quantitative heating power of different bodies such as carbon, hydrogen, etc., is known from experiment, and we are, consequently, in a position to say very closely from analysis, what will be the amount and the degree of heat which any untried fuel will give. The quantity of heat produced by the union of one pound of hydrogen with oxygen is four and a half times as great as that produced by the union of one pound of carbon with oxygen, but, because the product of the combustion of hydrogen, water, absorbs so much heat when raised to the temperature of combustion, compared with the amount absorbed by carbonic acid, the temperature produced by the combustion of the carbon is two and a half times as great as that accompanying the combustion of hydrogen.

Besides this amount and degree of heat which can be obtained from a fuel, several other properties have to be considered in estimating its usefulness for a given purpose. The amount of moisture which it contains when air dried is a very important consideration. Very many substances contain moisture which can only be driven out at a comparatively high temperature. That wooden cloths, for instance, though apparently dry, becomes damp when brought close to a hot fire, is a matter of common observation. Wood contains 80 per cent. of moisture, when air dried, that can only be driven out by exposure to a heat equal to that of boiling water. Peat and lignite, or brown coal, commonly contain about the same amount, while true coals contain very little, often no more than one per cent.

Amount of Ash.

The amount of ash contained in fuels is very variable. Wood contains but one per cent., while how much the mineral coals contain, depends on the circumstances under which they have been deposited. One of the commonest and most deleterious mineral admixtures in the deposits is iron pyrites—a sulphide of iron. When fuel containing this mineral is employed, for instance, in iron or copper smelting, the sulphur enters the metal to its great detriment, while in silver smelting it helps form a "matte" and thus causes loss of metal and increased complexity in the smelting operations. It has another property which has proved especially disastrous to San Francisco during the past year. Under the combined influence of air and water, it oxidizes to green vitriol. This change is really combustion, and is attended by the evolution of a large amount of heat. If, besides this condition necessary to oxidation, those necessary to the retention of heat are present—if the fuel is in a large mass, and confined, say in the hold of a ship, a temperature is reached, after a time, at which the coal will ignite. This is probably the cause of the loss of every one of the coal ships, which have failed to reach San Francisco during the past year. In a case that has come to my knowledge recently, the ship was tight, but the coal was wet when loaded. The ship just escaped by keeping the hatches open during the whole voyage. But vessels commonly leak more or less, and it is not always possible to keep the hatches open. The conditions of the oxidation point to the method of obviating these misfortunes. If the hold were built into the ship in such a way as to leave an empty space between its walls and the sides of the ship, and this space were kept well pumped out, cargoes of dry coal would be as safe as wheat cargoes. Wet coal a ship owner should shun as he would a mixed load of petroleum and matches. The climate in which a vessel sails makes little difference in the danger. This same property of pyrites has led to the ignition of many coal mines in Europe and America, to the destruction of hundreds of millions worth of property. Another important property of fuel is its coherence. Many sorts of brown coal, more particularly, falls to pieces on drying and will bear next to no transportation. Some lignites and some anthracites fall to powder when heated, thus choking the draught and causing much waste of fuel by dropping through the grate.

Flame.

One more property connected with the chemical constitution of fuels has much influence in controlling the use to which it is put—the length of the flame it gives. Fuel containing hydrogen in combination, when it is suddenly heated, evolves gaseous products, compounds of hydrogen and carbon, which are partly of a tarry nature and partly identical with illuminating gas. These gases burn as fast as they get to the air, but, as their bulk is considerable, they are swept to some distance from the solid fuel before being entirely consumed. Hence, arises a flame, such as we get from soft coal or wood. Carbon, uncombined with hydrogen, on the other hand, combines with oxygen when there is air enough present without going through an intermediate gaseous condition. If there is a want of air, as there always is in spots in a fire, the carbon combines in part with only half the oxygen which is necessary to the formation of carbonic acid. This half oxidized carbon is the poisonous gas known as carbonic oxide, but, as in ordinary fires, there is always a surplus of air present, comparatively little carbonic oxide is found and this is almost immediately burned to carbonic acid with the short blue flame we are accustomed to see in hard coal fires.

With these general facts respecting the nature of fuel in mind, it will be necessary for me to say but a few words about each separate species of natural fuel.

Wood.

Wood is the purest of fuels, and, neglecting the single per cent. of ash, contains in an air dried condition, 40 per cent. carbon, 40 per cent. combined oxygen and hydrogen, in the proportions in which they exist in water, and 20 per cent. of moisture. The hydrogen and oxygen being already in combination with each other, though, also, with a third substance, pass off in combustion as water, but produce no heat in doing so. In sudden burning, indeed, part of these elements form volatile carbon compounds, whence the flame of wood; but they ultimately unite again and the amount of heat obtained is the same as if they had existed in the wood as moisture. Hence wood has comparatively a very small heating power.

Peat.

Peat is the most recent of fossil fuels and is certainly very inferior, containing generally from 6-12 per cent. of ash and sometimes as much as 50 per cent., a larger proportion of which is often phosphorus and sulphur, the bane of the metallurgist, especially the iron master. Nevertheless, it is often of great service in regions where coal is scarce, and, by use for gas production, of which I shall speak presently, may, even when exceptionally poor, be made to do work which, but a few years since, the best of coal could not accomplish. The peats formed from the woody fiber of marsh grasses, shrubs and roots by a sort of partial decay under exclusion of the air, vary in appearance from a very light, almost white color, with unmistakable organic structure, through yellow and brown to pitch black, with no trace of organism. When firm enough the peat is simply cut out of the bog in blocks and dried in the air; when too loose in structure it is pressed or cut up by machinery and thus compacted. The hygroscopic moisture in peat is enormous, sometimes reaching 80 per cent., and when it is used for metallurgical purposes it is generally artificially dried. The substance of the peat contains more carbon than wood, and less oxygen, and the better sorts have considerably more heating power.

Lignite.

Brown coal or lignite, the only sort of coal found in this part of the United States, also varies much in appearance. It contains more carbon and less oxygen than peat, and has a considerably greater heating power. The large amount of moisture it contains, and generally its tendency to disintegrate injure its usefulness. Occasionally very small quantities of lignite are found which are indistinguishable from true coal, but these are only exceptional portions of deposits which have been particularly favored in their development. A peculiar odor accompanies the burning of brown coal, quite different from that produced by true coal, and its chemical behavior is also quite distinct. This is particularly the case with nitric acid, which turns brown coal into a yellow gum, while it scarcely affects the more completely fossilized fuel.

True Coals.

True coals are classified in a variety of ways for different purposes, such as coking and non-coking; bituminous, semi-bituminous and hard, and so on. Its most important properties to the metallurgist are its capacity or the want of it, to form solid cokes and the length of the flame it gives. In a shaft furnace we cannot use strongly coking coals, for those under the influence of heat, develop readily decomposable compounds of hydrogen and carbon, which deposit their carbon again in such a way as to ran the whole mass of fuel into a lump impenetrable by draught. In a shaft or cupola furnace, therefore, only anthracite or semi-bituminous coal can be burned. The semi-bituminous coal is, for the same reason, more convenient in a grate. The heating power of coal varies from 75-96 per cent. of that of pure carbon. Loam flaming coal is useful in reverberatory furnaces, or in any apparatus where the object to be heated is wholly or partly at some distance from the immediate coal. Inasmuch as the heat is distributed by the gradual combustion of the gases developed in the long flaming coal, of course it is less intense at the grate than where it is produced by an equivalent fuel giving but a short flame.

The necessity of having for cupola and crable furnaces a fuel which will give out as much of its heat as possible in its own immediate neighborhood, combined with a desire for a fuel possessing a great quantitative and qualitative heating power leads to the artificial carbonization of wood and coal. By subjecting these substances to a high degree of heat with the partial or total exclusion of air, the water, the oxygen and the hydrogen, are driven off and nearly pure carbon remains, which gives a great heat and little flame.

Charcoal.

Charcoal burning is usually done in rather a rough way, because, as only about 1/4 of the weight of the wood is obtained as charcoal, it is cheaper to make the coal where the trees are cut; and, of course the supply in any one spot is very limited. The sticks of wood are commonly piled on end, about a hollow box, which serves as a chimney, until a large heap of nearly hemispherical shape is formed. This is covered with sod and earth well beaten down and lighted from one or more sides. By means of holes made in the covering, sufficient air is admitted to maintain a slow combustion, a part of the wood being thus consumed to distill off the volatile matter from the remainder. The progress of the burning is easily told by the color of the smoke, etc., and regulated by closing or opening holes in the covering.

When the whole mass is turned to charcoal all openings are care fully close and the mass allowed to cool.

Since mineral coal occurs in immense masses permanent arrangements can be made for turning it into coke, commonly near the mouth of the main shaft of a mine. A great variety of furnaces have been used for this purpose, but those most approved to-day are long, horizontal passages, closed by doors at each end, and provided with flues in the sidewalls running the whole length of the furnace and opening into it. A hock of such furnaces are built together. When the furnace is in regular working, it is red hot at the time of charging. The heat develops gas in the charge of coal and the gas passes into the flues. These connect with the open air by dampers, or an equivalent, and with a chimney, as well as with the furnace. By allowing air to enter the flues the gas is burned there in the wells of the furnace, thus maintaining its heat, and the distillation is by this means continued until the coal has all become coke. The doors of the furnace are then opened and the whole mass of coke is pushed out by machinery and quenched with water. Brown coal and peat can only be coked with special precautions and at great expense, and the attempt is hence rarely made.

Fires in Grates.

The combustion of fuel on a grate is at the best but a very imperfect operation. If we admit just air enough to consume the fuel, the lumps are sure to be so arranged that an excess of oxygen is present at some points and too little at others; consequently we get imperfect combustion and smoke, and, at the same time, have unconsumed air to be heated at the cost of fuel. All the water present, either in a free or combined state, must be evaporated and heated to the temperature of the furnace, and the fire is capable of very little regulation. When the fuel is fine, or poor, these difficulties are magnified; a point soon comes when they are unsurmountable, and a material known to have great heating power in it, must be rejected for burning purposes.

Gas.

The greatest improvement of the century in metallurgy was the introduction of the use of gas to overcome these difficulties. As we have already seen, carbon combines with oxygen to carbonic oxide, if but little oxygen is present and this gas again combines with oxygen to carbonic acid, if it gets an opportunity. By piling a deep grate two or three feet deep with fuel, or what amounts to the same thing, filling a low cupola furnace with fuel and allowing no access of air from above, we get the conditions needful for the production of carbonic oxide. At the same time we avoid any superfluous supply of air; the water, however, is distilled in the same way as in an ordinary grate. By cooling the gas down, either by passage through a long pipe, or through something like a low pressure steam engine condenser, the water may be precipitated and a dry gas obtained. If this gas be now admitted into a furnace with air sufficient to burn it we get a smokeless flame, containing little or no water and capable of regulation by turning dampers just as easily as a gas jet. If in addition, we force the air and the gas, after it has been cooled to precipitate the water it carries, to go through a heating apparatus a flame of the utmost intensity can be produced—an intensity quite unattainable by the ordinary imperfect combustion of coal.

It will probably occur to you that much heat must be used up in this conversion of the carbon in the gas producer into carbonic oxide gas, and there certainly is; but the combustion of carbon to carbonic oxide develops much less than a third of the heat liberated when carbon burns to carbonic acid, and, consequently, we have over two-thirds of the potential heat of the fuel employed disposable in the furnace while the mechanical conditions in the ordinary furnace are so inferior that even with good fuel there is a large gain in reducing the carbon to a gaseous form. When when we come to inferior fuels, the advantage is simply infinite for, so far has the art been developed, not only with coal, or even with peat, but with saw dust a heat can be produced with which wrought iron can be melted like lead, while the utmost that an ordinary furnace with the very best of English coal can do is to make it come what sticky.

I recommend the subject of heating with gas most especially to your attention. California is unfavorably situated with regard to fuel, and, if, as no doubt will be the case, this becomes a manufacturing country, the use of gas will assume a greater importance here than it has as yet done in any country.

MONTANA MINING DECISION.—The Secretary of the Interior has affirmed the decision of the Land Office in the case of the application for the patent for the General Lode, situated in Montana. The decision says that all lode claims must be governed by the laws in force at the date of the location, and cannot exceed 10 feet of surface width, unless the local laws at that time will permit.

The hydraulic mines in many portions of Placer county have suspended for want of water, but the prospect now is that there will be no further trouble.

NEXT season promises to be a busy one for Humboldt. Everybody is making preparation to open a piece of mining ground.

A NUGGET weighing 68 ounces was recently taken out of the Bald Mountain mine, in Sierra county.

USEFUL INFORMATION.

The Alchemists.

What manner of men were the alchemists? How did they preserve, cultivate and transmit the wonderful delusions of their creed? We have endeavored in a former chapter to show that the idea of transmutation arose from the old Greek idea of the conversion of one element into another; and the belief in the possibility of transmutation once admitted, the pursuit of the alchemist would naturally follow in a mystical and credulous age. As to the men themselves their character was twofold; for there was your alchemist proper, your true enthusiast, your ardent, persevering worker, who believed, heart and soul, that gold could be made, and that, by long search or close study of the works of his predecessors, he could find the Philosopher's stone; and there was your knavish alchemist, a man who had wit enough to perceive that the search was futile, and impudence enough to dupe more credulous people than himself, and wheedle their fortunes out of them on pretence of returning it tenfold in the shape of a recipe for converting lead into gold. Of the true alchemist we have many pictures. The alchemist, the astrologer, the mystic, the wizard, were men of the same stamp. They often practiced the same arts side by side. The same habit and altitude of thought belonged to one and to all, and became all equally well. Take the dreamy, mandarin, semi-magical Althotas, who had been described so well by Dumas: "An old man, with gray eyes, a hooked nose, and trembling but busy hands. He was half buried in a great chair, and turned with his right hand the leaves of a parchment manuscript." Note also his intense abstraction, his forgetfulness of the hour, the day, the year, the age, the country; his absolute and intense selfishness and absorption, the concentration of the whole powers of his soul upon his one object. Or let us look at Victor Hugo's Archidiaire de St. Josias, in his search for the unseen, the unknown, and the altogether uncanny; the bitterness of his soul, his passionate musings, his conjurations and invocations in an unknown tongue; his own self, that wonderful mixture of theologian, scholar, mystic, perhaps not much unlike the diviae S. Thomas Aquinas himself.

"If we peep into Dom Claude's cell, we are introduced to a typical alchemist's laboratory—a gloomy, dimly-lighted place, full of strange vessels and furnaces and melting pots; spheres and portions of skeletons hanging from the ceiling; the floor littered with stone bottles, pans, charcoal, aludels and alembics, great parchment books covered with hieroglyphics; the bellows with its motto—'Spira, Spira'; the hour glass, the astrolabe, and over all cob webs and dust and ashes."

Chalcedony.

What boxwood is to the wood engraver—the means without which the finest art would be impossible—that chalcedony is to the engraver of gems. Hard without brittleness, susceptible of a fine and enduring polish, tinted by nature with beautiful, and at times, strongly contrasted hues, or capable of taking such colors at the hand of man, it has been from the earliest period of art not only the favorite medium but the only possible medium of the gem engraver's most striking effects. In its simplest state chalcedony is an unattractive white stone, nearly transparent, and chiefly useful for making spear-heads and arrow-tips, or there more modern representatives, gun-flints. Sometimes it has a striped or banded appearance, due to alterations of more or less translucent layers, ranging in color from very white to the white of skim milk, still not very serviceable for gems or jewelry. When stained by metallic oxides, however, chiefly those of iron, it raises to the dignity of gemstone, isard, cornelian, chrysoprase, etc., which, uniformly tinted brown, yellow, red or green, as agate, onyx, sardonyx, etc., when the colors lie in bands or strata, or are separated by layers of white. The natural formation of these flowers of the mineral world is recorded in their substance. Though commonly found in lavas and other igneous rocks, or in the debris remaining from their disintegration, gemstones are substantially an aqueous product, and require the agency of fire simply to develop their fine colors, a step in their production more the work of art than of nature.

Rosewood.—It has puzzled many people to decide why the dark wood so highly valued for furniture should be called rosewood. Its color certainly does not look like a rose, so we must look for some other reason. Upon asking, we are told that when the tree is first cut the fresh wood possesses a very strong, rose-like fragrance, hence the name. There are half a dozen or more kinds of rosewood trees. The varieties are found in South America and the East Indies and neighboring islands. Sometimes the trees grow so large that planks four feet broad and ten in length can be cut from one of them. These broad planks are principally used to make the tops of pianofortes. When growing in the forest, the rosewood tree is remarkable for its beauty, but such is its value in manufactures as an ornamental wood, that some of the forests where it once grew abundantly now have scarcely a single specimen. In Madras, the Government has prudently had great plantations of this tree set out, in order to keep up the supply.

Cement Walls and Cisterns.

With one pint of quick lime or good (new) cement, we use from one to two parts of coarse, sharp sand, to make a stiff paste. This for quality, depends on the freshness of the lime or cement, which requires less sand in proportion to its strength. Sand is useful to diminish the cracking, as the paste or mortar dries, thereby to give it "body" and help fill up. Quick mortar should be made up every day, for each day's work, which is contrary to practice in this country, but the mortar is better. It never becomes soft after use, from age. Into this, fine and coarse gravel can be worked by the trowel, as the joints are finished. For cisterns, Rosendale and Portland cement takes the place of lime, with only less sand, and makes walls as solid as Ransome stone. The magnesia of the cement seems to have a peculiar affinity for unburnt limestone and brick surfaces.

Finely pulverized soft brick, mixed with about equal parts of wood ashes and a little water in a basin, is put on the surface of a cement-laid or grouted floor of a dwelling house, with a trowel, and worked up to a finish that much resembles a glaze on pottery. This is easily swept and washed, and wears always a clean appearance. As a paste to repair old cisterns and stop cracks, with or without the addition of a small quantity of iron filings and sal-ammoniac, this is very valuable.

We wish it were possible to impress our masons with the fact that thin joints make the best walls, and require the least quantities of water and cement, both of which are chemically stronger and better for being mixed for the purpose.

To RENDER GLASS OPAQUE OR FROSTEN.—According to *Dingler's Journal*, a sheet of ordinary glass, whether patent plate or crown does not matter, is cleaned; and if only portions of it are to be frosted, those are left bare, while the others are protected by mechanical means in any simple manner. Some floor spar is rubbed to a fine powder and mixed with concentrated sulphuric acid, so as to make a thin paste, and this is then rubbed by means of a piece of lead upon those parts of the glass required to be rendered opaque. A fine frosted outline or design may thus be produced upon a sheet of smooth transparent glass. To finish the operation, the glass is gently heated in an iron vessel covered with a funnel passing up the chimney, to get rid of the noxious fumes that are given off; on cooling, the plate is washed with a dilute solution of soda or potash, to remove any acid yet remaining, and is then rinsed in water. Focusing glasses for the photo camera, and development glasses for pigment printing, can be prepared in this way at very little expense.

CHINESE VERMILION.—It is a singular fact that none of the vermilions of commerce equal in perfection of tint that made by the Chinese. They make it from fine cinnabar—sulphuret of mercury—which has been carefully unblended, and is deposited in beautiful, bright, violet-red crystals. The latter are powdered between two stones, being ground with very little water; the mass is then washed repeatedly with pure water, the purity of the water being deemed of the first importance. Immense quantities are used by the Chinese in making ink, painting on porcelain and wood, and coloring candles, paper, etc. It is put up in black papers, and forms an article of large export, the prices depending on that of mercury, it being about twenty-five per cent. higher than the latter.—*N. Y. Sun.*

GOOD HEALTH.

Organic Matter in Water.

Water enters so largely into everything that relates to life and health, that we ought never to tire of the study, especially of all the sanitary phenomena connected with that element. The *London Chemical News*, in reviewing a recent French scientific work, by Henri de Parville, makes the following interesting and suggestive extracts and remarks:

"How does organic matter become dangerous? The phenomenon is complex. The organic matter in suspension or in solution creates in the water a peculiar medium, suitable for the development of exceedingly small beings of the genus *Vibrio*. It is no longer mere water—it is a world of microscopic animals and plants which are born, live, and increase with bewildering rapidity. The infusoria find in the water calcareous, magnesian, and ammoniacal salts, and their maintenance is thus secure. Drink a drop of this liquid and you swallow millions of minute beings. There are those which are capable of eating up putrefaction in our tissues. These are our enemies; often our mortal enemies. Let water be placed in contact with organic remains capable of nourishing these malignant *vibrios*, and it at once becomes more dangerous than any poison."

The author points out that, according to the researches of the late Dr. Calvert, charcoal, lime, and permanganate of potash, contrary to the received opinion, facilitate putrefaction and actually promote the formation of animalcules. Charcoal when used for the purification of polluted waters, undoubtedly absorbs into its pores offensive gases held in solution, as well as liquid coloring and flavoring matters. It can render such waters colorless and tasteless.

But upon living animalcules and their germs it is absolutely powerless. Nay, water containing a known amount of "albumenoid ammonia" when experimentally filtered over animal charcoal has been found on analysis worse than before. Permanganate of potash may oxidise—in fact, burn up—dead organic matter suspended or dissolved in water; but upon living organisms it is almost powerless. We have seen animalcules remain in full life and apparent vigor for hours in water to which permanganate had been added in a large proportion. M. Davaine found that putrid blood after treatment with charcoal became more putrid than before. It is possible that the gases dissolved in the liquid hinder the development of the infusoria. The author considers carbolic, or better still cresylic acid, as the only agent which extricates these animalcules. According to Woehler, alumina in the gelatinous state precipitates the dissolved animal matter which serves as a pabulum for these minute animal and vegetable beings. The experiments of M. Davaine on the power of antiseptics to destroy the virus of carbuncle belong rather to medicine than to chemistry. Solution of iodine seems the most effectual remedy.

How to Distinguish Good from Poisonous Mushrooms.

So many deaths or severe cases of poisoning occur from eating poisonous mushrooms, that it is very important to know how to distinguish the good from the bad. The following is given by Prof. Bentley, which, though not full or unerring, gives the general characteristics which the edible or under trees and poisonous species of fungi may best be distinguished:

The edible mushrooms grow solitary, in dry, airy places, and are generally white or brownish; they have a compact, brittle flesh; do not change color, when cut by the action of the air; juice watery, and odor agreeable; taste not bitter, acrid, salt or astringent.

The poisonous mushrooms, on the contrary, grow in clusters in woods, and in dark, damp places, and are usually of a bright color; their flesh is tough, soft and watery, and they acquire a brown, green or blue tint, when cut and exposed to the air; the juice is often milky, the odor commonly powerful and disagreeable, and the taste either acrid, astringent, acid, salt or bitter. These characteristics are almost invariable.

For the Too Thin.

You would like to be round and rosy-cheeked. Go to bed early after having spent the evening socially. Cheerfulness and content are the best friends of healthfulness. Sleep in a pure atmosphere and in a room into which the sun has shone through the day. Don't be afraid of the night air, for there is no other air at night, and you would certainly die before morning if you did not breathe it; avoid draughts and dampness; sleep as long as you can and get up as soon as you wake, if you feel rested. Drink all the pure cold water you can swallow first and ride or walk in the open air for half an hour; then eat a breakfast of Graham bread, baked sweet apples with cream, or some other fruit, with a soft, fresh-boiled egg, or a bit of beefsteak and a baked potato, and drink a glass of new milk, if you like it.

Enjoy what you are doing, either for itself or what it will bring you. Breathe as much pure air as possible, bad food and pure air will make flesh faster than impure air and good food. For dinner, eat roast beef or mutton, or rare steak, with bread, potatoes and all vegetables that are relished, a desert of plenty of ripe fruit, with cream and sugar, but without pastry or cake. If tired, rest a little before dinner, and take a short nap after it. Don't work hard enough to produce excessive perspiration, if you can help it, or until you feel very much exhausted.

For supper eat oat-meal porridge, cracked wheat, or Graham mush, with cream and fruit, and a fresh roll; or, if you don't feel hungry, take a glass of milk and eat nothing. Drink little tea or coffee, or none at all. Bathe every day to keep the skin clean and in a surprisingly short time you will grow plump and light-hearted. But remember, you must laugh to grow fat.—*Milwaukee Magazine.*

WEAR AND REPAIR OF THE BRAIN.—The notion that those who work only with their brains need less food than those who labor with their hands has been the cause of untold mischief. Students and literary men have often been the victims of a slow starvation, from the ignorance of the fact that mental labor causes greater waste of tissue than muscular. According to a careful estimate, three hours' hard study wears out the body more than a whole day of work on the anvil or farm. "Without phosphorus, no thought," is a German saying; and the consumption of that essential ingredient of the brain increases in proportion to the amount of labor which the organ is required to perform. This wear and tear of the brain are easily measured by careful examination of the salts in the liquid excretions. The importance of the brain as a working organ is shown by the amount of blood it receives, which is proportionally greater than that of any other part of the body. One-fifth of the blood goes to the brain, though its average weight is only one-fourth the weight of the body. This fact alone would be sufficient to prove that brain-workers need more food and hotter than mechanics and farm laborers.—*Builder.*

DOMESTIC ECONOMY.

Good Food for Working Men.

How much pleasure is lost and how much material is wasted by a lack of intelligent cooking, too many think that neither science nor art has anything to do with the duties of a cook. And yet we all know from pleasant as well as sad experience, that some cooks will prepare a most tempting repast from materials, which in the hands of another, will come out to the table so ill prepared as to need a most ravenous appetite to induce one to eat.

The hard work of the farmer or mechanic so sharpens his appetite; the rugged health of the family caused by abundant exercise in the open air and the multitudinous duties of the housewife, all lead us to fall into careless habits in the selection and preparation of our food.

While we are aware that economy on every hand is necessary to the success of the farmer above every other class of working men, we can see not the slightest reason why he should not live well. There are many delicacies within his reach. He can have his varieties of fresh garden vegetables, his plentiful supply of poultry, fresh eggs, choice gilt-edge butter, milk and cream in abundance, plenty of fruit, etc. Why should he live poorly? Because in far too many instances all these resources from a lack of intelligent and pleasing cooking are not used to advantage.

The housewife does not use the material at her command understandingly. The bread will be made always in the same way. The potatoes will be boiled for every meal in stereotyped fashion; the meats ditto, and the farmer's table which could be most invitingly supplied, is generally coarsely laid.

This is not always from a lack of knowledge, as is proven by the inviting repasts which are temptingly placed upon the table when company is invited. But in such households it is due to a careless lack of forethought and a want of appreciation of good food.

Scientific economy is lost sight of in our living. How seldom do we stop to count the cost of a meal, or of any particular plan of living. We do not recommend extravagance in food, but ask the lady members of our Order to give careful intelligent thought to the preparation of their meals.—*Husbandman.*

TO STEAM A TURKEY.—All of us are used to roast and boiled turkey, but a steamed turkey is more of a novelty, while it is also a most delicious dish. Cleanse the fowl thoroughly, then rub pepper and salt well mixed into the inside of it. Fill up the body with oysters mixed with a small cupful of bread crumbs. Sew up all the apertures; lay the turkey into a large steamer and place over a kettle of boiling water, cover closely, and steam thoroughly for two hours and a half. Now take it up; set the platter in a warm place, and turn whatever gravy there is in the steamer, straining first into the oyster sauce which you have prepared in the following manner: Take a pint of oysters, turn a pint of boiling water over them in a colander. Put the liquor on to boil, skim off whatever rises to the top. Thicken it with a tablespoonful of flour rubbed into two tablespoonfuls of butter; season well with pepper and salt. Add two or three tablespoonfuls of cream or milk to whiten it, and pour it over the turkey and platter; serve boiling hot. This sauce must be made while the turkey is still in the steamer, so that it can be poured over the turkey as soon as it is taken up.

SNOWFLAKE CAKE.—Take a half cup of butter, two cups of white sugar, four cups of flour, one cup of sweet milk, three eggs, one teaspoonful of cream-of-tartar, and one-half of that quantity of saleratus. Stir butter and sugar together, add the beaten yolks of eggs, and half the flour with the cream-of-tartar in it; turn in nearly all the milk, dissolve the saleratus in what is left and add it. Beat the whites of the eggs and mix in; stir in remainder of the flour. Bake in jelly-cake tins. Grate the meat of two fresh coconuts after paring off the outer skin; add to them one cup of sugar and the beaten white of two eggs. Spread between the cakes, which should have been baked in three pans. Heap the cocoanut very high on the top of the uppermost cake and scatter sugared almonds among it.

POTATO FRITTERS.—Boil two large potatoes, mash them well, beat four yolks and three whites of eggs, and add to the above, with one large spoonful of cream, another of sweet wine, a squeeze of lemon, and a little nutmeg. Beat this batter half an hour at least. It will be extremely light. Put a good quantity of fine lard in a stewpan, and drop a spoonful of the batter at a time into it. Fry them; and serve with a sauce composed of a glass of white wine, the juice of a lemon, one desert spoonful of peach-leaf or almond water, and some white sugar warmed together, or the common wine sauce.

GERMAN APPLE PUDDING.—Take a deep tin pudding dish and cover it with a layer of the best pie crust. Have some good, tender apples cut fine, and spread over the paste; a layer of apples, with sufficient sugar for sweetening, and cinnamon and nutmeg to taste; again a layer of apples, etc., until your dish is filled, when you pour over it a tea-cup full of cream, add your cover and bake to a light brown.

Mineral Statistics.—California's Position.

In another column we give some remarks on
the subject of bullion products and the dissat-
isfaction with which the present system of com-
piling statistics in mining matters is regarded.
Still, as will be seen by what we have said of
the product of Colorado mines in another part
of this issue, even those directly interested
disagree. It never was pretended that Wells,
Fargo & Co. gave us complete mineral statistics.
They only gave us the product of the precious
metals. Iron, coal, copper, quicksilver, borax,
antimony, lead and other mineral products are
not taken into consideration at all, although
the work done and results accomplished by
mines of this character are important. In
other countries mineral products of all kinds
are included in statistics of this character, but
on this coast only precious metals are taken
account of. In fact, we really need reliable
mineral statistics, not figures of bullion product;
but these can only be collected by the Govern-
ment itself.

What we desired more particularly to call
attention to, however, is the fact that statistics
collected yearly by Wells, Fargo & Co., refer
only to the precious metals, and by no means
give an idea of the advancement of mineral
development. It would be very interesting if
we could get at the real value of the mineral
products of all kinds of the States and Terri-
tories. That would give a better idea of what
miners are doing, and of the value of the min-
ing interests. For instance, California was
credited this year with a bullion product of
\$20,300,531, and the ore and base bullion were
estimated at \$1,715,550. Now, the Selby works
refined 12,000 tons of base bullion, mostly from
California mines, valued at about \$960,000.
The silver in this would probably bring its
value up to \$2,000,000. The copper shipped
from here in 1874 was valued at \$67,400. The
coal produced by the Mount Diablo mine was
valued at about \$1,500,000. The value of
quicksilver mined is difficult to estimate, but
the figures must be large. The export by sea
was 5,504 flasks, of 76½ pounds each. The
railroad carried from this city 432,635 pounds
and 36,444 pounds from San Jose. This alone
at \$1.50 per pound would be worth nearly one
and a-half millions of dollars. Many of the
mines in Sonoma and Napa counties have
contracts with large mines on the Comstock,
and ship direct from mine to mine; so these
shipments would not appear in the statistics of
shipments for this city.

This was not all by any means, as we know
that seven of the mines produced 1,457,488
pounds of quicksilver in 1874, and there are 42
producing mines in the State, with 49 furnaces
running. The mines which produced that

amount are leading ones, but all the rest of the
42 are producing also. This is a product of
\$2,186,232 for seven mines, calculating the
quicksilver at \$1.50 per pound. The other 37
mines have at least produced enough to bring
the product up to \$3,000,000, and more proba-
bly will bring it up to \$3,500,000 in value.

So, although, California is only credited with
a mineral product of \$20,300,531, she pro-
duced base bullion and silver worth \$2,000,000;
coal worth \$1,500,000; copper worth \$67,400,
and quicksilver worth \$3,000,000 at the lowest
estimate. This makes a total mineral product
of \$26,867,931, instead of \$20,300,531.

In the estimate of Colorado given in another
column, the coal, lead and copper are included,
and then it foots up \$6,962,383; while by sim-
ply adding our mineral products given above,
not included in the California statistics of
Wells Fargo & Co., the increase for California
comes within \$94,983 of equaling the whole
product of Colorado. The papers in that state
complain of injustice in having their product
decreased by Wells, Fargo & Co.'s statistics,
and we mention these facts to show that none
of the States or Territories are justly represented
as to their mineral development. The Califor-
nia mining interest really produced \$6,567,400
more than they are credited with, and account
is only taken of the principal mineral products.
Even at that figure the estimate is small.
Considerable copper is used by the acid and
bluestone factories, which is not considered
above. The Lincoln and other coal fields
produced large quantities of coal not taken into
consideration. We have also made a narrow
estimate in counting the quicksilver mines here
in 1874 at \$3,000,000.

The other States and Territories are all in
the same fix as far as the bullion product sta-
tistics misrepresenting them is concerned;
but we have no doubt that California suffers
the most, as the value of her quicksilver, alone
would probably exceed all the miscellaneous
mineral products of any other individual
State or Territory west of the Mississippi.
At present there is no method of collecting
these statistics, or rather no means for collect-
ing them; so each individual State must con-
tinue to be misrepresented until the Govern-
ment takes the matter in hand, and he content-
ed to know that the misrepresentation is on the
right side of truth as stating the product at less
rather than more than it really is.

The Patchen Process.

Considerable interest has been manifested in
mining circles during the past week in the new
process of amalgamation, some results of
which have been published. The process was
patented recently through the MINING AND
SCIENTIFIC PRESS Patent Agency, by Mr. Abel
Patchen. Experiments have been made by
Prof. Thomas Price and Louis A. Garnett, of
the San Francisco Assaying and Refining
Works, in order to test the process, the results
of which we give below. We may state here
that further improvements have been made, and
the necessary apparatus is now being arranged
in order to give more thorough tests of the
process. These experiments will be made in
this city.

We append the result of working eight tons
of Belcher ore by the Patchen process, in
charges of 2,000 pounds each, occupying five
hours to each charge.

Result from 8 tons of Belcher Ore, worked by Patchen Process.

Average per ton.....	\$209.77	\$128.72	\$38.49	\$1.26	\$0.37	\$16.07	\$30.00	\$6.5	\$9.25

Mr. Garnett says: "For the purpose of com-
parison I have examined into the milling re-
sults obtained by the process heretofore and at
present employed on the Comstock ores; and
while I find that certain mills occasionally ob-
tain 75 to 80 per cent., the average is between
65 and 70 per cent. only. For November, the
average results of the Belcher from 12,334

tons, assaying \$55 per ton, was 66½ per cent.,
and for December, from 12,200 tons, assaying
\$45 per ton, 67 per cent., being respectively
28½ per cent. and 26½ below the results given
above. [In dollars this would be \$195,443
and \$145,954 less than the result by Patchen
process.—Eds. Press.] Only two companies
seem, however, to have furnished in their an-
nual reports the gold and silver in the pulp as-
say, separately, which is necessary to deter-
mine accurately the percentage of the re-
sults obtained. These are the Hale & Norcross
and the Savage, and they confirm each other
to a remarkable degree.

We append the results of the working of ore
from the Hale & Norcross and the Savage, re-
ferred to by Mr. Garnett in the upper of the
two tables. Assuming from the data obtained
from the upper table that the present average
production of bullion from Comstock ore
does not exceed 70 per cent., and that 90 per
cent. can be produced by the Patchen process,
the difference in the aggregate yield from the
ores produced during the past year will be seen
by the lower table. Adding to this the saving
of \$2.50 per ton of quicksilver, makes the total
saving for each if the new process had been in
use.

Working Results of Hale & Norcross and Savage Mines.

Without going into details of the process, it
may be stated that its introduction into any mill
will not necessitate the purchase of any new
and expensive machinery. As further tests
will shortly be made in this city, we will keep
track of the improvements and give our read-
ers a full account of all that is done.

Dr. BECKER'S LECTURES.—We give in an-
other part of this issue the last lecture, hut one,
delivered by Dr. Becker, on "Quicksilver and
Fuel." The last lecture delivered by him con-
cluded his part of the course. It was on
"Steel," but the crowded state of our columns
prevents even a synopsis being given. These
lectures of Dr. Becker's have been interesting
and instructive, and show that he has a thor-
ough knowledge of his subjects. We understand
that he intends remaining in the city to pursue
his profession, and as there is a fine field here
for good metallurgists, no doubt he will find
plenty to do. Although he has been here only
a short time his name has been brought promi-
nently before the mining public through his
connection with the University and the course
of lectures. There is plenty of room here for
those who understand metallurgical processes
thoroughly, and we only wish there were more
of them.

DURING the month of January, 19,747 tons
of ore were shipped over the Virginia and
Truckee railroad. Owing to storms, damage
to the railroad track and land slides, 2,254 tons
less ore were shipped than during the prece-
ding month.

Product of Colorado Mines.

The press in most of the Territories is com-
plaining that the figures given of the bullion
production of 1874, by Wells, Fargo & Co., are
entirely too small. We speak of this subject of
bullion production in another column, giving
some of the reasons why it is difficult to get at
the exact yield. Colorado complains of in-
justice in this direction and wants to be set
correctly before the miners of the coast. The
Miner, published at Georgetown, Colorado, in
stating that we have published Wells, Fargo &
Co.'s report of bullion production, protests
against misrepresentation of the Colorado min-
ing industries. We gave the yield of Colorado
in 1874 at \$4,191,405, and the *Miner* says the
lowest just estimate that can be made of Colo-
rado's yield is \$6,000,000. It says the yield of
Clear Creek and Gilpin counties alone was \$4-
413,265.

To show that even those who should be best
informed on this subject are liable to error, we
may state that the different Colorado papers
disagree as to the total bullion product. The
Miner says the product for 1874 was \$6,000,000;
the *Mining Review* says it was \$5,362,383. The
Miner says that Clear Creek and Gilpin coun-
ties alone yielded \$4,413,265; the *Mining Re-
view* gives the yield of these two counties at
\$3,835,810. The Central City Register gives the
yield of Gilpin county alone as \$2,808,803, as-
suming that the bullion shipped by the Boston
& Colorado Smelting Works was all derived
from ores from mines in that county. This
was probably not the case and the *Mining Re-
view* says the Register's figure are \$1,176,940
too large. The *Mining Review's* totals, includ-
ing coal, copper, etc., foot up \$6,962,383, as the
whole product of Colorado for 1874.

It will be seen from this that all these papers
disagree as to the exact production. The sta-
tistics of the *Mining Review* seem to have been
prepared with considerable care and are those
which will be used by the U. S. Mining Com-
missioner. The placer and gulch mining inter-
ests show a decided improvement. The ship-
ments of matte and ore abroad have fallen off.
The product as given by the *Mining Review* is as
follows:

Gold Bullion from Smelting and Amalgamat- ing Works.....	\$ 422,563
Silver Bullion from Smelting and Amalgamat- ing Works.....	1,983,207
Gold Bullion from Stamp Mills.....	1,297,425
Gold Bullion from Placer Mines.....	382,500
Ore and Matte shipped out of the Territory.....	1,102,815
Pig Lead.....	73,676
Copper.....	100,197
Total product—Coin.....	\$5,362,383
To this may be added Coal.....	1,600,000
Grand Total.....	\$6,962,383

The figures representing the value of coal
should not be taken into consideration when
comparing them with those of other States or
Territories, as the statistics are usually intended
only to embrace the precious metals. It will
be seen that the figures given above are more
favorable for Colorado than those of other
States or Territories as both lead and copper
are included as well as coal, which is not usu-
ally done. We have spoken more at length on
this subject in another column under the head
of "mineral statistics." It is extremely difficult
to get at the exact bullion product, and less in-
justice has been done to Colorado, with figures
given by Wells, Fargo & Co., than has been
done to Arizona; but still the statistics of
Wells, Fargo & Co. must be taken as a basis
for calculation until some system of collecting
them is devised by the Government.

The Burleigh Drills in Sierra County.

The Burleigh drills and air compressors have
rapidly come into use on this coast since their
first introduction here, and have given
great satisfaction. At the Sutro tunnel, in
Nevada, they have made some wonderful pro-
gress with this machinery, excelling any tun-
nelling work ever before accomplished. A
number of mines in California are now using
the drills, and we give below a summary of
the results accomplished by the Golden Star
company last month.

The superintendent furnishes the report on
the working of the machinery in the Golden
Star tunnel, near Alleghany, Sierra county,
for the month ending January 30th, 1874, of
44 shifts work. The ground is a cement mixed
with crystalline trap and granite boulders.
The machinery used is one stoping drill and a
No. 1 compressor.

Size of Tunnel.....	7x7
Total holes drilled.....	758
No. of feet drilled (in 758 holes).....	2,653
Size of holes.....	1½ inches
Actual distance tunnel driven.....	111 feet
Average depth of holes.....	3 feet 6 inches
Average speed of drilling per hour.....	10 feet
Average time occupied drilling per shift.....	3 hrs 45 min
Coal consumed per 24 hours (green cedar). 7½ of a cord	
Steam pressure.....	65 pounds per square inch
Air pressure.....	65 pounds per square inch

All this time the hoiler was standing in an
open shed without steam jacket or lagging.
The lubricants consumed for the month were
three gallons of oil, ten pounds of tallow and
one pound of kerosene. The stoppage for
repairs to the machinery for three months has
been 15 minutes; cost, 50 cts.

The first train ran through the Hoosac tun-
nel on the 9th inst. It was composed of three
gravel and two passenger cars with 100 passen-
gers. The passage was made in 25 minutes.

Economic Botany.

Lecture Delivered before the University of California College of Agriculture on Wednesday, Jan. 20, by Prof. C. E. BRASER, M. S., of the Iowa College, Ames, Iowa.

[Reported expressly for the PRESS.]

The Grasses.

Graminaceae. This is a large order of 4,000 species distributed universally over all regions and climates; in temperate or cooler climates forming a close mat or turf. In the tropics growing in bunches or tufts.

The size of plants of this species varies from one or two inches in height to 100 or more feet for example, the bamboo. (It would be well to experiment upon the culture of this last in California.) Their stems contain sugar and their seeds starch; and these contribute more to the support of man than any other of the orders. They yield abundance of food for both man and beast. But few of them have poisonous properties or principles. Very few of these have poisonous seeds.

There is a marked distinction between grasses and the allied forms,

Sedges and Rushes.

One difference is that sedges have no nonribbed stem in them and are hollow inside. Another distinction is that grasses have two-ranked stems, while sedges have three-ranked. Another distinction is the stem of sedges is usually triangular; that of the grasses is usually round or flat. A grass is then a round, hollow-jointed stem with narrow leaves which are borne upon an open sheath. The flowers are quite small in structure and on account of the small size of the parts their analysis is usually more or less puzzling to the student. The unit of the inflorescence is a spikelet. A spikelet consists of two glumes at the base, with from one to half a dozen flowers above. See Fig. 1.

This family is divided into three groups; viz: 1. Cereals. 2. Forage plants. 3. The canes. The cereals are those grasses which are cultivated for their seeds. They are all annuals. Rice, *Oryza sativa* is a native of Asia. The annual importation of this commodity into California is thirty millions of pounds, 90 per cent. of which comes from China. It furnishes food for more people than any other of the cereals. South Carolina rice is considered the best. The plant itself grows to the height of from two to three feet. It requires a good deal of moisture and unless rains are frequent, or means of irrigation are at hand, it will prove unproductive. The common variety requires for its successful cultivation a wet marsh, and matures in from four to six months. It is sown in drills and a few inches of water is alternately let on and drawn off; this being continued for some days to supply the requisite moisture. At the top it has a panicle inflorescence somewhat like that of the oat plant.

Wheat, *Triticum vulgare*, stands next in importance to rice. It has been cultivated for many thousand years; so that its nativity is doubtful. We do not know what it was when it was a wild plant. (It is probably the cultivated form of a rather weedy grass, found in the Mediterranean basin, *Egilops ovata*. Its stem contains a large amount of silica, to which is due, its strength, and on account of which it requires for its fullest development a very silicious soil. On account of its easy variability it can be grown in almost any climate; in Europe as far north as 60 degrees. It now has very many forms. The spring and winter wheats come from the same original and one can readily be changed into the other, especially on this coast. Each has a bearded and a beardless species, and each species of both has a white and a red variety. The size is variable.

Spring wheats are grown in the severer climates; the red varieties containing more nitrogenous matter, being harder than the white ones. Winter wheat grows in a mild climate. California wheats lie about midway between the two; that is, spring and winter wheats. According to the statistics of last year, ninety-five per cent. of California's wheat was exported to England, and was valued at fourteen millions of dollars. At *a*, Fig. 1, may be seen a longitudinal section of a grain of wheat, showing at *x* a representation of the germ.

Barley, *Hordeum vulgare*, is undoubtedly a native of Southwestern Asia, and has been cultivated up to 67 deg. north latitude. This plant has also for thousands of years given food to man and beast. It is less nutritious than wheat, having less gluten; hence it has passed out of use as food for man, and is now only used as the food of animals, and in the manufacture of beer and other malt liquors. Its range is wider than that of any other cereal, and it adapts itself easily to climate and soil; but thrives best on moist soils. California exports are increasing; and from present indications this grain will for the next few years be

A Valuable One for the Farmer to Raise.

Rye, *Secale cereale*, is a native of the Mediterranean basin, and is now grown in almost every place where the wheat plant is grown. It is harder than the wheat. It is grown as food

for man, and in some places for domestic animals also; but is most largely used in the manufacture of spirituous liquors; for which use it is peculiarly fitted by its chemical composition. The California crop of this grain is light and unimportant.

Oats, *Avena sativa*, is of uncertain nativity, but thought to be of some part of the Eastern continent. It is of a wide range, about equal to that of barley, and is used mostly as food for the domestic animals. In cool climates it is used by man.

Indian corn, or Maize, *Zea Mays*, is a native of America. It is now cultivated in all warm regions. There are many varieties, which allow of profitable cultivation throughout a wide range of latitude. Its uses are many, for man and beast; being used as food, and also in the manufacture of spirituous liquors. It has 88½ per cent. of fat-forming principles; 1½ per cent. of flesh-forming principles; 9 per cent. of water, and 1½ per cent. of salts. It is of most importance in the Mississippi valley. At *b*, Fig. 1, is shown a longitudinal section of a grain of corn, with (*x*) a representation of its germ.

The Forage plants, or, what are popularly called grasses. For successful growth, different climates and soils require different species. Very many differ as to their value, according to the uses to which they are to be applied. Mr. Flint says: "Some grasses contain more nutritive matter when green; others when the seed is ripe and dry. Some flourish in elevated lands; others in low lands. Some prefer clay and some light soils. Some are solitary. No one grass combines all the qualities which we want; hence, we never grow one alone." In general, that grass makes the best forage which has

The Greatest Amount of Leaf

To a certain amount of stem; though the stem must always be strong enough to prevent breaking down or lodging. The principal grasses in the United States are the following: Meadow foxtail, *Alopecurus pratensis*, grows from two to three feet high, resembles Timothy and is valuable for hay. It has an erect, smooth, cylindrical spike; grows on calcareous loam; comes early and endures cropping well. It grows well in England and would probably do well here. This grass forms a close sod after a few years. It is best for hay at the time of flowering. Timothy (often called herd's grass), *Phleum pratense*, is a native of the Eastern United States, resembles Meadow foxtail, but is longer and taller. It grows on moist, loamy soils, or even on peaty soils, but does not vegetate well on sandy or gravelly soils. It is late in growth, forms an indifferent sod and does not bear close cropping. Cattle turned upon it tread it down too much. It is most nutritious some time after flowering. Common experience agrees with chemical analysis in placing this

Among the First in the List

Of valuable forage grasses.

Red top, or fine top, etc., *Agrostis vulgaris*,

Fig. II.

a, spikelet; *b*, a single flower, both of *Poa pratensis*, i. e., Kentucky Blue Grass.

is a native of Europe, and possibly of the United States. It is a branching, panicle grass, with slender stems. It grows well in moist soils, producing valuable hay; makes a good sod and endures cropping pretty well. This grass is probably not as nutritive as some other kinds, for cattle leave it untouched when they have a choice between it and some of the other cultivated grasses.

Orchard grass, *Dactylis glomerata*, is a native of Europe. It is a tall, panicle grass, with the flowers produced in dense clusters; grows well on all soils; is rather coarse, but furnishes an abundance of quite good fodder. As it is early in blossoming, it can be advantageously mixed with the early blooming clovers. It should be cut while in blossom. In cropping it should be fed close, or the stems become too tough and wiry. This grass does not form a good sod, but is inclined to grow in tussocks. It endures drought well and it grows well in the shade and hence derives its name, being so well

Adapted to Culture Where Trees are Grown.

Kentucky blue grass, or June grass of the East, *Poa pratensis*, is a smaller grass, with spreading panicle, stem thin and fine, leaves long and narrow. It grows well on moist loam; while on sandy soils, it is small and wiry. It requires a moist climate for its full development, and then it is one of the most valuable pasture grasses. In Kentucky, it is used almost to the exclusion of other grasses; but in the drier climates and more sandy soils of the States farther to the north, it is of but little value. Where this grass thrives, it forms a close, tough sod and is

Well Adapted to Lawns.

Chemical analysis made by Professor Law of the Royal Agr. Society of England, shows the

nutritive value of the grasses just noticed to be as follows:

FORAGE PLANTS.	Water.	Flesh forming principles.	Fatty Matter.	Starch, gum, etc.	Woody Fiber.	Mineral substances.
*Meadow Foxtail, or (<i>Alopecurus pratensis</i> .)	80.20	2.44	.52	8.89	6.70	1.55
*Timothy, or (<i>Phleum pratense</i> .)	57.21	4.86	1.50	22.85	11.32	2.26
*Red Top, or (<i>Agrostis vulgaris</i> .)	no data
*Orchard grass, or (<i>Dactylis glomerata</i> .)	70.00	4.06	.54	13.20	10.11	1.59
*Kentucky Blue grass, or (<i>Poa pratensis</i> .)	67.14	3.41	.56	14.15	12.49	1.85
*Green. †Dry	10.25	2.83	43.06	38.02	5.94

This table will show the method of investigation; and yet there are so many other things to be taken into consideration, that it would be folly to decide upon the merits of a grass simply from an examination of its chemical composition. Its earliness and adaptability to soil and to climate must be taken into consideration. Still, such analysis will serve as guides to the practical experimenter. There is great need for further experiments, both chemical and "field"—to determine the value of our native grasses, such as the *Muhlenbergias*, *Diarrhena*, *Koleria*, *Eatonia*, *Bunch* grass of the plains, and many others growing both in the wooded and the open country.

The Canes

Include three, which are of special importance. Sugar cane, *Saccharum officinarum*, is a native of tropical Asia. It is a tall-growing, perennial grass, propagated by cuttings from top joints, and produces the sugar of commerce. Chinese sugar cane, *Sorghum nigrum*, a native of China, is a smaller and less valuable plant. It is now extensively cultivated in parts of the United States. Broom corn, which has panicles of such branching form as

Fig. 1.

a, longitudinal section of a wheat grain; *b*, similar section of a grain of corn. At *xx* in both the little germs are shown.

to furnish good material for brooms, is of the variety known as *Sorghum vulgare*.

Among the

Weeds

Which belong to the family of grasses, may be included Chess, or Cheat, *Bromus secalinus*, so well known by farmers as growing among wheat; Couch grass, or Quack grass, *Trisetum repens*, which has an underground spreading growth, making it hard to get rid of; Bristly foxtail, *Setaria viridis* and *Setaria glauca*, which will become weedy, especially if allowed to grow wild; Barn-yard grass, *Panicum crus galli*, and others.

Ornamental Species

Include Pampas grass of South America, *Gynerium argenteum*, which is adapted to a mild climate; Ribbon grass, *Phalaris arundinacea*; the Bamboo, *Bambusa arundinacea*, a native of India, is a remarkable grass, growing to the height of fifty or seventy feet in two or three months. This species grows to the height of 100 feet; attaining a diameter of from three to six inches.

Several kinds of grasses are beneficial to man in the manufacture of cordage and paper. Others are valuable for litter; for green manuring—that is, to plow under and enrich the soil—for holding the sands on beaches, and for many other uses.

The best book treating upon this subject is "Flint's Grasses and Forage plants," which I commend to your favorable notice.

THE JAPANESE are about to do something with the petroleum in their country, and a delegation accompanied by interpreters, have been making a tour of inspection among the Pennsylvania oil wells. They have purchased an outfit of boilers, engines etc., for sinking, to be shipped to Japan.

THE MINING excitement in Potter Valley is running high. They have found gold, silver, and perhaps quicksilver. It is said that there is not a foot of the hills surrounding the valley north, east, west or south, but what has been staked off for a mining claim.

News from Tybo, Nevada, is of an encouraging character, and appearances indicate that in a short time it will give as good an account of itself as any town in eastern Nevada.

H. L. SHANO claims to have discovered a rich cinnabar lode within one mile of Lang's station, near the mouth of Soledad cañon, Los Angeles county.

THE numerous iron mines in the vicinity of Ogden, Utah, are being developed with much vigor, and are said to be looking fine.

THE furnace at Newark, Nevada, has been shut down for repairs, and the further improvement in its construction.

THE Carson mint coined \$347,660 last month.

Saving Fine Gold.

In our issue of December 12th, 1874, we called the attention of the mining public to a new method of saving fine gold, which was shortly to be tested here practically. We refer to the apparatus invented by Mr. J. Tunbridge, and known as the "Gold Trap." At that time we gave a brief description of this simple machine, and stated that it would shortly be tested practically at one of the large quartz mills at Grass Valley. Mr. Tunbridge, the inventor, brought one of these traps from North Carolina, where it has been at work successfully on \$2 rock, thinking that he could prove to California miners that his machine would be a valuable one to them. He took the proper steps to show his faith in his "gold trap," by attaching the apparatus to a first-class mill in a prominent district, so that the miners there could see for themselves what could be accomplished.

Naturally, many miners have taken a lively interest in the working of the machine. The difficulties attending any new amalgamating process are readily understood by mill men. In this case there were some 100 square feet of metallic surface to be got into working or "taking" condition, acquiring a considerable deposit of gold. Again, quicksilver takes up from one and a quarter to one and a half per cent. of gold, that amount passing through the strainer, with the quicksilver.

The trap was placed at the end of the flumes of one of the best managed mills—the Empire—which has oscillating concentrators at the end of the battery plates, for saving fine gold and quicksilver. Many thought at the Empire mill, that no gold would be found beyond these devices. Others thought differently, and that it would prove the efficiency of the trap if gold could be caught below. Of course there are many mills which use no concentrators, and at these the percentage of gold passing the plates would be larger.

The "trap" was put into operation under these circumstances, the slimes running through it uninterruptedly without either labor or attention for eleven days, and a few short intervals. A slight clean-up was made, showing a few ounces of amalgam and considerable gold deposited on the large surface of copper, making that metal more active for future use. There was also some gold in the quicksilver which passed through the strainer.

Having shown that the trap was a success, the inventor was desirous of moving from an inconvenient distance from town to a more favorable location, and at the same time wished to give the trap a trial at some hydraulic mine. The opportunity has been afforded him by Capt. Miller, of the Dartmouth mine and Cement mill, near Grass Valley. Some necessary alterations have been made in the trap, although its capacity can be increased to carry any amount of slimes, the one in operation being able to carry 50 inches of water. After testing the process there at some of the larger gravel claims, it is the intention of Mr. Tunbridge to dispose of patent rights in the machine at terms which will be profitable to purchasers.

OREGON MINES.—Parties in from the quartz mines on Rogue river report great excitement there, occasioned by recent developments in the Hawk McNair mine. Active measures are being taken to secure a road from the mines, to intersect the stage road at Grave Creek. Numerous prospecting parties are out. Several veins have been struck, some of which promise well.

THE Consolidated Virginia company are putting up a new set of boilers at their boiling works, in addition to those already in use. They do not wish to be delayed by any accident which may happen to the boilers now in use. How nice it is to have a "honanza" to fall back on. You can get extra engines, boilers etc., even before you need them. However, in a big mine it pays to take all precautions to prevent delays and stoppage of work, if only for a few hours.

CONSIDERABLE indignation exists in mining circles in Salt Lake on the discovery that certain persons are attempting to obtain a special franchise from Congress for a toll road in Little Cottonwood Cañon. The miners and mine-owners of the district will send a remonstrance against the proposed invasion of their rights.

UTAH has in successful operation thirty-one silver-smelting furnaces, four arrastras, one separating and one refining work, four concentrating works and thirteen silver mills.

THE Inyo Independent estimates that the shipments of ores alone from that county would furnish \$15,000 worth of freight per day to a railroad extending from the mines to tide-water.

IT HAS been practically demonstrated that roofing slate of the best quality can be obtained in El Dorado county.

THE Renton coal mines at Seattle (W. T.) are again in full operation, crowding matter to full capacity.

AUSTIN shipped bullion valued at \$76,219.93 during January.

JOHN TAYLOR & CO.

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they
 have no equal. No effort has been, or will be spared
 to have them constructed in the most perfect manner
 and of the great number now in operation, not one has
 ever required repairs. The constant and increasing de-
 mand for them is sufficient evidence of their merits.
 They are constructed so as to apply steam directly
 into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:

The pan being filled, the motion of the miller forces
 the pulp to the center, where it is drawn down through
 the aperture and between the grinding surfaces. Thence
 it is thrown to the periphery into the quicksilver. The
 curved plates again draw it to the center, where it
 passes down, and to the circumference as before. Thus
 it is constantly passing a regular flow between the grind-
 ing surfaces and into the quicksilver, until the ore is
 reduced to an impalpable powder, and the metal amal-
 gamated.

Sellers made on the same principle excel all others.
 They bring the pulp so constantly and perfectly in con-
 tact with quicksilver, that the particles are rapidly and
 completely absorbed.

Mill-men are invited to examine these pans and sellers
 for themselves, at the office, 229 Fremont Street,
 San Francisco.

BALL'S

SWEEPING DREDGE,
A NEW AND VALUABLE

CALIFORNIA INVENTION,
 Has been very lately well proven by per-
 forming a job of dredging at the mouth of
 San Antonio Creek, at Oakland, Cal.

There is but this one machine that has ever had these
 improvements employed. It is an old machine, for-
 merly built for another device, and is unfavorably con-
 structed for Ball's improvements; yet this first tempo-
 rary experimental machine has filled a scow of eighty-
 five cubic yards in sixteen minutes in unfavorable dig-
 ging. For durability, digging hard material and fast
 work, it has a reputation (supported by leading engi-
 neers) as having no equal.

Testimonials and references will be given on appli-
 cation to the inventor, who is the sole owner of patents
 (excepting having made an assignment of the one ma-
 chine now belonging to the Central Pacific Railroad
 Company) Having resolved not to sell any rights
 unless upon a basis of actual work performed by a
 machine built by myself for the purpose of fairly es-
 tablishing the worth of the invention, I therefore offer
 to sell machines or rights on the following plan, which
 is warranting the capacity of the machine by actual
 work:

I will enter into an agreement with any responsible
 party to build and sell a machine, scows and tender,
 all complete, and right of all my improvements in
 dredging machines throughout the Pacific Coast for
 \$20,000, warranting the machine to dredge six cubic
 yards per minute (to fill a scow at that rate). \$20,000
 will but little more than pay the cost of building the
 machine, scows, etc., all complete; therefore I am pro-
 posing to ask nothing for my patents unless my machine
 dredges more than six cubic yards per minute. But
 it shall be further agreed that in case (at a fair trial to
 be made within a stated time) the machine shall fill
 a scow at the rate of more than six cubic yards per
 minute, then \$10,000 shall be added to the price above
 stated for each and every such additional cubic yard
 thus dredged per minute, and for additional fractions
 of a cubic yard thus dredged in the same ratio the
 \$10,000 is to be added to said price above stated.

I will sell any other Territorial or State rights (either
 United States or Foreign) upon the same plan and at a
 lower price proportionately than the rights for the
 Pacific Coast.

I will sell a single machine with scows and all com-
 plete, and right to use the same in a limited territory,
 for \$20,000 on the same plan as above stated, but will
 add only \$2,000 to each additional yard over the six
 cubic yards per minute. Each machine is not to em-
 ploy more than two 10x20 inch engines.

Payments to be made in U. S. gold coin on delivery
 of machine, as may be indicated by agreement.

Address,

JOHN A. BALL,

Ayer's Hair Vigor

—FOR—
RESTORING GRAY HAIR
 TO ITS NATURAL VITALITY AND COLOR.

Advancing years, sick-
 ness, care, disappoint-
 ment, and hereditary
 predisposition, all turn
 the hair gray, and either
 of them incline it to shed
 prematurely.

Ayer's Hair Vigor, by
 long and extensive use,
 has proven that it stops
 the falling of the hair
 immediately, often re-
 news the growth, and always surely restores its color,
 when faded or gray. It stimulates the nutritive organs
 to healthy activity, and preserves both the hair and its
 beauty. Thus harsh, weak or sickly hair becomes
 glossy, pliable and strengthened; lost hair regrows with
 lively expression; falling hair is checked and established;
 thin hair thickens; and faded or gray hair resumes their
 original color. Its operation is sure and harmless. It
 cures dandruff, heals all humors, and keeps the scalp
 cool, clean and soft—under which conditions, diseases
 of the scalp are impossible.

As a dressing for ladies' hair, the Vigor is praised for
 its grateful and agreeable perfume, and valued for the
 soft luster and richness of tone it imparts.

TEATS' PATENT FURNACE

For Roasting, Desulphurizing, Chloridizing and Oxidizing Ores, etc. For the reduction of Gold, Silver, Lead and other ores, saving a larger percentage, at less cost, than any other invention now in use. Chloridizing Silver ore more thoroughly, in less time, with less fuel, salt and labor; also roasting Lead ore preparatory to smelting, better and cheaper than any other invention. The Furnace is so constructed that one man, of ordinary ability, tends five or more furnaces; controls them with ease; adding heat or air; stopping or starting at will; charging and discharging with ease. Also, Patent "Conveying Cooler," for conveying and cooling roasted ores, beating the water for amalgamation and the boilers at the same time. Saving the large space in mill (covered with brick or iron), and the labor of two men per day, exposed to the poisonous chlorine gases. Also, Patent Air Blast "Dry Kiln," for drying ores direct from the mine or breaker, saving fuel and labor heretofore necessary in drying ores for dry pulverizing. For description refer to MINING AND SCIENTIFIC PRESS, No. 18, October 31, 1874. For particulars address

D. B. MILLER & CO.,
No. 12 West Eighth Street, Cincinnati, Ohio
Circulars, &c., will be furnished, if required.

KNOWLES' PATENT STEAM PUMP.

It has no Cranks or Fly-Wheel, and has no dead points where it will stop, consequently it is always ready to start without using a starting-bar, and does not require hand-work to get it past the center. Will always start when the steam cylinder is filled with cold water of condensation.

CENTRAL PACIFIC R. R., OFFICE OF THE GEN'L MASTER MECHANIC,
SACRAMENTO, CAL., January 14, 1873.

A. L. FISH, Esq., Agent of the Knowles Steam Pump—Dear Sir: In reply to your inquiry as to the merits of the Knowles Steam Pump, in use upon this road, I will say that it gives me great pleasure to report that they have performed their work well whenever called upon. In no instance have they failed. We have now over 30 of them in use on this road as fire engines, and pumping water for shop and station use. I consider the Knowles Steam Pump the best in use, and prefer it to any other.

Yours, truly,
A. J. STEVENS, General Master Mechanic.

A. L. FISH, Agent Knowles' Steam Pump—Dear Sir: In answer to your inquiries, we state that the big best award for Steam Pumps at the Eighth or last Mechanics' Fair in San Francisco, was a FIRST PREMIUM and Diploma, awarded to Knowles' Patent Steam Pump, as published in the Official List September 23d, 1871.

A. S. HALLIDIE, President Board of Managers.

PATENT

ELASTIC PEN-HOLDER.

This Holder is furnished with a pair of elastic rubber air-chambers, which render a steel pen as flexible as the old-time goose quill pen.

Provide an easy hold, that does not cramp or tire the fingers.
Protect the fingers and desk from ink stains.
The fingers acquire a delicate touch that enables a person to obtain a beautiful hand-writing.
The elasticity of the pen can be adjusted to suit any hand, by simply sliding the pen up or down.
Sent by mail, on receipt of Seventy-Five Cents.

F. I. CURRY,

Late Foreman of the Vulcan Iron Works, Proprietor

High and Low Pressure Boilers of all Descriptions.

SOLE MANUFACTURERS OF THE CELEBRATED SPIRAL BOILER.

SHEET IRON WORK of every description done at the Shortest Notice.

All kinds of JOBBING and REPAIRING promptly attended to. 17v25-3m

THE RISDON
Iron and Locomotive Works,
INCORPORATED.....APRIL 30, 1868.
CAPITAL.....\$1,000,000.

LOCATION OF WORKS:

Corner of Beale and Howard Streets,
SAN FRANCISCO.

Manufacturers of Steam Engines, Quartz and Flour Mill Machinery, Steam Boilers (Marine, Locomotive and Stationary), Marine Engines (High and Low Pressure). All kinds of light and heavy Castings at lowest prices. Cams and Tappets, with chilled faces, guaranteed 40 per cent. more durable than ordinary iron.

Directors:

Joseph Moore, Jesse Holladay, O. E. McLane,
Wm. Norris, Wm. H. Taylor, J. B. Haggins,
James D. Walker.

WM. H. TAYLOR.....President
JOSEPH MOORE.....Vice-President and Superintendent
LEWIS R. MEAD.....Secretary
24v17-qy

FULTON
Foundry and Iron Works.
HINCKLEY & CO.,
MANUFACTURERS OF
STEAM ENGINES.

Quartz, Flour and Saw Mills,
Hayes' Improved Steam Pump, Brodie's Improved Crasher, Mining Pumps, Amalgamators, and all kinds of Machinery.

N. E. corner of Tehama and Fremont streets, above Howard street, San Francisco. 3-qy

Empire Foundry,

Nos. 137, 139 and 141 FREMONT STREET, SAN FRANCISCO.
RICHARD SAVAGE, Proprietor.

Heavy and light Castings of every description. House Fronts, Mining and General Machinery estimated and constructed at shortest notice. On hand the celebrated Occident and French Ranges, Burial Caskets, Grates and Fenders, Road-Scrapers, Hydrants, Tugue Irons, Ploughwork, Sash Weights, Ventilators, Dumb Bells, Gipsies, Ship Castings, SOIL PIPE of all sizes, Fittings and Cauldron Kettles in stock at Eastern rates. SHOES and DIES a specialty. Ornamental Fences in large variety. 4v30-lyr.

UNION IRON WORKS,
Sacramento.

ROOT, NEILSON & CO.,

MANUFACTURERS OF

STEAM ENGINES, BOILERS,
CROSS PATENT BOILER FEEDER and SEDIMENT COLLECTOR

Dunbar's Patent Self-Adjusting Steam Piston PACKING, for new and old Cylinders.

And all kinds of Mining Machinery.
Front Street, between N and O streets,
SACRAMENTO CITY.

G. W. PRESCOTT.

W. R. ECKART.

Marysville Foundry,

MARYSVILLE, CAL.
PRESCOTT & ECKART,

Manufacturers of Quartz and Amalgamating Machinery, Hoisting Machinery, Saw and Grist Mill Irons, House Fronts, Car Wheels, and Castings of every description made to order. 9v23-ly

Miners' Foundry and Machine Works,

CO-OPERATIVE,

First Street, bet. Howard and Folsom, San Francisco

Machinery and Castings of all kinds.

PARKE & LACY,

SOLE AGENTS FOR THE

Burleigh Rock Drill Company.

—MANUFACTURERS OF—

PNEUMATIC DRILLING MACHINES,

AIR COMPRESSORS AND OTHER MACHINERY.

Also, Farmers' Dynamic Electric Machine and Hill's Exploders for [Blasting, Putnam Machine Company's Tools, Wright's Steam Pumps and Haskin's Engines.

Address

PARKE & LACY,

21v28-3m-hd

310 California St., S. F.

DATA OF CAMERON'S PATENT STEAM PUMPS, REGULAR SIZES.

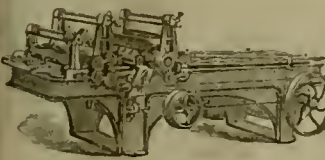

DAVID STODDART, Agent. 114 BEALE ST., SAN FRANCISCO.

NUMBERS.	0	1	2	3	4	5	6	7	8	9

California Planers and Matchers, and Wood Working Machinery of all Kinds,

For Sale at TREADWELL & Co. Machinery Depot, San Francisco.

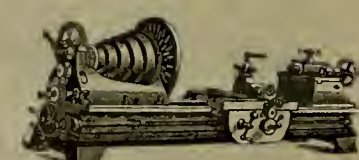

The CALIFORNIA PLANNER and MATCHER is gotten up from new patterns specially for this Coast. It has Cast Steel Slotted Cylinder Head, running in patent self oiling boxes; Matcher Spindles also of the best cast steel. The gears are all protected with iron covers. Will plane 24 in. wide and 6 in. thick, and tongue and groove 14 in. wide. Will make rustic and stick gutters, or heavy mouldings, etc., and is the best Job Machine ever built.

Adjustable Saw Gauge.

Improved Saw Arbors.

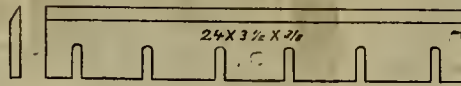

Iron Working Machinery.

Foot Power Jig Saws.

Improved Band Saws.

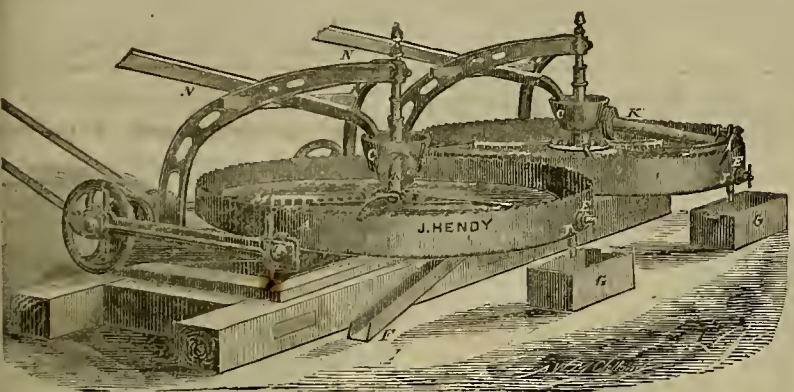

Planer Knives of all sizes on hand.

Lathes, Planers, Drills, etc.

TREADWELL & CO.,

San Francisco

OVER \$3,500 PER MONTH SAVED
BY THE USE OF
Hendy's Improved Amalgamator and Concentrator

Can be seen at the Manufactory, No. 32 Fremont Street, San Francisco.

SAN FRANCISCO, April 27, 1872.

JOSHUA HENDY, Esq.—Dear Sir:—As a practical miner and millman, I take pleasure in recommending the use of your Concentrators in all mills where gold or silver ores are reduced. No mills should be without them, for the following reasons:

1st. They are good sizers (no perfect concentration in pulverized ores can be effected without first sizing).

2d. The best Concentrator I have ever known—(the concentrated stuff only containing 5 per cent. of sand).

3d. They are good amalgamators, light (feathery) particles of amalgam and particles of coated gold by attrition are brightened, and from their specific gravity and the action of the pan, fall to the bottom and adhere.

4th. They require but little power and attention to run them, and with ordinary care will last for years.

I have been familiar with the workings of your Concentrators for four years past; have run them myself in the North Star Mine, Grass Valley; am familiar with their practical workings on the Empire Mine, Grass Valley; St. Patrick, Placer Co.; St. Lawrence, El Dorado Co.; Oaks and Reese, Mariposa Co., and most cheerfully give you this testimony. For further information you are at liberty to refer to,

Yours respectfully,
JAS. H. CROSSMAN, M. E.

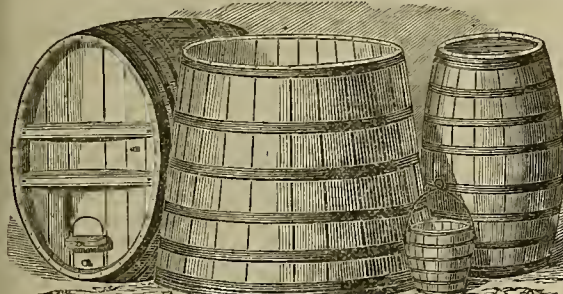

409 California street, or Cosmopolitan Hotel.

OFFICE SUPERINTENDENT OF KEYSTONE CON. M. CO., AMADOR, AMADOR COUNTY.
MR. J. HENDY—Dear Sir:—In answer to your inquiries as to your Concentrators furnished our company last July, I would say that I am more than pleased with them; and the saving to the company has been over \$1,500 per month more than with the blankets and huddles formerly in use.
O. C. HEWITT, Supt.

OFFICE SUMNER MINE, KERNVILLE, April 27, 1874.
J. HENDY, Esq.—Dear Sir: Having four of your Concentrators in use at our Mills for four or five months, which for saving Amalgam and for concentrating Sulphurets, are a success, beyond a doubt, I feel it a duty due you and those interested in Quartz Mills, to recommend them.
As further evidence of their worth, I now order TWELVE more of your Machines for our new Mill, now in course of erection.
E. R. BURKE, Superintendent.

For description send for Circular.

CENTENNIAL PACKING.
SELF-LUBRICATING.

FOR Locomotive Marine and Stationary ENGINES.

FOR Steam Pumps AND Hot or Cold Water Pumps OF ALL KINDS.

The CENTENNIAL is composed of the finest Hemp, made in strands or sections, of different sizes, each being saturated in a composition of pure German Black Lead and Tallow and covered with a braiding of the best Italian Hemp to be found in the market. It is manufactured in a shape the most convenient to use and handle, and gives from 50 to 100 per cent. more length compared with an equal weight of other makes. It runs with less friction on the rod than any other Packing made, from the fact of its being so perfectly soft and pliable, and so well lubricated so to require a minimum pressure on the rod. It cuts off smooth and makes perfect joints, is easily adjusted to any size rod, and only requires occasionally a new ring to keep the stuffing box full. ENGINEERS, TRY IT. For sale in any quantity by TREADWELL & CO., San Francisco.

IMPORTANT TO LUMBERMEN.

\$100.00 IN GOLD.

And FIRST PRIZE SILVER MEDAL were awarded to us for the best

SAWS

In the great National contest held at Cincinnati, September, 1874, and lasting over six days. Our celebrated DAMASCUS TEMPERED SAWS were declared the victors.

We have made special shipping arrangements for very low freights and quick dispatch of our saws for the Pacific Coast. ONLY SEVEN DAYS BY MAIL FROM SAN FRANCISCO. Send your address for a full report of the great National Sawing Contest, and the class of saws that you use, with the thickness, size and kind that you use, and specify such as you will require within the next 60 days. We will guarantee to furnish you with saws that have no equal in quality, and at prices that will be entirely satisfactory. Address

Improved Cast and Forged Steel Shoes and Dies for Quartz Mills.

(PATENTED MAY 26TH, 1874.)
Price Reduced to 16 Cents Per Pound.
SAN FRANCISCO, November 10th, 1874.

To Supts. of Quartz Mills and Mining Men generally:

We take pleasure in stating that owing to the rapid increase in our orders, our Pittsburg Manufacturers have been compelled to add largely to their works—a new gas furnace and heavier trip hammer—and are thus enabled to reduce the cost of steel and at the same time produce SHOES and DIES superior to any yet manufactured. We have consequently reduced the price to 16 cents per pound and solicit a trial order, guaranteeing that you will find them at least 10 per cent. cheaper than the best iron. There are no STEEL SHOES and DIES made excepting under our patent and sold at this office, or by our authorized agents, though certain Eastern manufacturers advertise STEEL SHOES and DIES which are only cast iron hardened by the addition of a composition. They will not out-wear two sets of common iron, though called steel. They are very brittle and are not capable of being tempered, flying from under the hammer like cast iron. Our STEEL SHOES and DIES are in use in many of the largest mills on the Pacific Coast, and all who have tried them pronounce them cheaper and far superior to iron in every respect, even at the old price of 20 cents per pound. Their advantages over iron are cheapness on first cost, increased crushing capacity, time saved in changing and in setting tappings, increased value of amalgam by absence of iron dust and chippings, and a saving of 75 per cent. in freight. It takes 50 days to fill orders from the manufactory East. Price 16 cents per pound shipped at San Francisco. Terms liberal.

Address all orders, with dimensions, to
CAST STEEL SHOE & DIE CO., Room 11, Academy Building, S. F.

TREADWELL & CO.'S (IMPROVED) Upright Safety Engines and Boilers.

(MADE BY THE NEW YORK SAFETY STEAM-POWER COMPANY.)

We call particular attention to the graceful designs and simple mechanism of this Engine Boiler; the form is not only pleasing to the eye, but is also, that which secures the greatest strength and rigidity with a given amount of material. The Boilers, which are of the Upright Tubular style, with internal fire box, are of the best material and are constructed in accordance with the latest improved designs. The leading surface and area of grate are in excess of the quantities usually allowed for the same power, and it is therefore unnecessary to purchase a greater rated power than is actually required, while in cases of emergency these boilers can be depended on for more than their rated power. The Engine is not fastened to or upon the boiler, and is mounted on a separate cast-iron frame, which is overhauled by the boiler, and is not subject to the heat from the boiler. The high speed which is necessary for economy of fuel, all parts are easily accessible—a great advantage. Is complete in itself as a Portable Engine and Boiler, or the Engine can be detached from the boiler and run independently, if required. Its main points are simplicity, safety and small repair or machine shops, or for hoisting, wherever a small and safe power is already in use.

THE "HOADLEY" PORTABLE STEAM ENGINE

From
3 to 40
Horse
Power.

ALL SIZES
Hoadley's
PORTABLE ENGINES
Sole Agents
TREADWELL & CO

The above cuts represent the new style "HOADLEY" variable cut-off 15 Horse-Power Portable Engine. We have same style and size mounted on wheels as a Threshing Engine for the Russell End-shake Separator. We have all sizes from 3 to 40 horse-power on hand. The HOADLEY ENGINES need no recommendation from us. We have sold them in California for 20 years, and every year has added to their improvements. The last great improvement is the Cut-off Governor, thus giving them all the economy and increased power of the most thorough built stationary engine.

Millmen, Mine-owners and Mining Superintendents, and all who intend buying engines, will do well to examine carefully the merits of the "HOADLEY" before purchasing. Circulars and prices sent free on application. Address

MILLS FURNISHED AT SHORT NOTICE

At the lowest Market Prices.

Cazin's Combination Ore-Sizer and Con- centrator—One Plunger System.

[Covered by Letters Patent of July 2d, 1872, and recent applications.]

Containing a sizing apparatus, (revolving screen) deliv-
ering two or four sizes of ore to two or four rows of
sieves, each row independent of the other, and each
having 5 sieves, each row concentrating according to
specific gravity the special size automatically fed into
it, resulting in the simultaneous continual delivery of
separated materials, working 2d and 3d-class ores into
1st-class ores of perfect cleanliness. It thoroughly sepa-
rates native gold or copper from quartz or any other
lode matter—galena and silver sulphurets from
pyrites, baryta and quartz; and pyrites from quartz.
Added to a battery of stamps these machines consti-
tute a full system of ore concentration, sufficient in
most cases for the requirements of western mines, with
a capacity of 15 or 20 tons per 24 hours.

VOLUME XXX
Number 8.

Hydraulic Mining in California. No. 13.

Excavation.

In digging the ditch along the mountain slopes the safety of the ground as to slides must be well examined, and the real body of the ditch must be always dug in solid soil, and far enough in the side of the mountain to leave at the outside or lower bank a level surface on which to place a part of the soil of the bank and the ditch.

The bank on the mountain side must be carried on a good slope at once, so as to prevent slides from it, which, during the rainy season, would otherwise occur, not only filling the ditch but causing great and dangerous breaks, since the water, checked in its course, would run over the lower bank, causing damages which would take much time and money to mend.

No operation connected with hydraulic mining needs greater care and foresight than the building of a ditch. The best constructed ditch will cause a great deal of trouble for the first year or two, but an indifferently constructed ditch will cause not only as much repairing as the first costs amount to, but be forever after a second hand affair.

Deep ditches are preferable to shallow ones, as the evaporation during the summer heat is far less in the former than in the latter. Still, before deciding on the depth of a ditch—whether two or three feet deep—it will be well to examine the soil through which it has to be dug. If the country bed-rock is covered only with a little soil, and if a ditch two feet deep would avoid the bed rock, economy dictates the two foot ditch made wider.

All ravines or small water courses crossed by the line of ditch must be secured in such a way that their water can either be admitted into the ditch or carried over it, as it is wanted or not. Regard must be had in this respect for the increasing volumes of water during the rainy season. It is a notorious fact that the quantity of water carried by established ditches during the summer season is reduced by nearly one-third in its volume by the time the point is reached where the water is to be used. It may be true that in many cases the low state of the river from which the water is drawn is partly the cause of this reduction in volume; but in other cases, where the river affords an unlimited amount, the diminution of the water must be ascribed altogether to evaporation and leakage.

The question arises whether it would not be advisable to counteract this lessening of the water by building the ditches wider at their head and reducing their width for a distance of a few miles till the normal size is reached. In the winter season only a quantity answering the size of the lower part of the ditch would be admitted at the head. In summer all the water the upper part of the ditch could carry would be admitted and brought along, even filling the ditch to the top of the lower (artificial) bank—which would be safe enough in summer. This plan seems well calculated to practically increase the capacity of ditches.

Trees.

Trees found on the line of the ditch, the removal of which is necessary, must never be cut down so that only the stumps remain. To grub up these stumps is a most difficult, tedious, and expensive work, and can be avoided by undermining the tree on the lower side, cutting its supporting roots and felling it down the hill, tree, stumps, roots, and all.

Flumes.

The flumes on the line of the ditch may be built either on a little less grade, or a little smaller, than the ditch, as the smoothness of the boards causes less friction than a rough ditch, and the water, therefore, runs faster.

Flumes are generally built of one and a half

inch plank, with a framing of four by four and three by four scantling for every two and a half or three feet. The strength of the scaffolding for the flumes must be conditioned by their height, and left to the discretion of the builder. The foundation of this scaffolding ought to be on very solid ground, and, if possible, little exposed to water in puddles, coming and going, as the season changes. Moreover, the bottom part of the supporting posts, or the sleepers, ought to be well charred, as mentioned before, to prevent rot and subsequent settling of the flume. High flumes ought to be well anchored with strong wire, or wire rope, to protect them against winds.

Where a flume is to be built, the underbrush, fallen trees, etc., ought to be cleared away—by ax, or fire, or both—to protect the flume against the conflagrations which occur in our forests from time to time during the dry season.

Flumes of sheet iron are highly recommended.

thousand vertical feet, formed by the gorge through which the West Branch of the North Fork of Feather river flows. This enterprise was a complete success, and found as such a deserved publicity, which makes its particular description at this place unnecessary. For the sake of handy reference, however, it may here be said that the pipe is made of the best sheet iron, as follows: No. 14 iron was used for 150 feet pressure; No. 12 iron was used for 275 feet pressure; No. 10 iron was used for 350 feet pressure; No. 7 iron was used for 425 feet pressure; one-fourth iron was used for 600 feet pressure; five-sixteenths iron was used for 850 feet pressure; three-eighths iron was used for 900 feet pressure.

A cistern with sand boxes, which serves as receptacle for sand and gravel carried from the ditch, is constructed at the receiving point. An elbow of the pipe dips here in the water, to prevent, as much as possible, the entrance of

S. N. KNIGHT'S IMPROVED HURDY-GURDY WATER WHEEL.

ed. The iron could be protected against corrosion by immersion in Dr. Angus Smith's preparation of coal-tar, and would certainly afford a very durable and incombustible material. When the present high price of iron shall have fallen to near its former rate, this material will undoubtedly be used with great advantage.

The building of flumes should be avoided as far as possible, since, under the most favorable conditions, using the best kind of sugar pine lumber, a flume will only last from ten to twelve years; and the cost of its repair is computed to be 75 per cent. higher than that of a ditch.

A flume carrying a constant stream of water is far less exposed to decay than one which carries water periodically. The alternate swelling and shrinking of the wood in the latter not only destroys the fiber of the wood, but also draws the nails, and thus injures the structure.

Iron Pipes.

The use of iron pipes as aqueducts is not a novelty in California. As early as 1856 or '57 an iron pipe of 40 inches diameter was laid across a small depression at Timbuctoo, near Smartsville, Yuba county. The city of San Francisco is supplied by the Spring Valley Water company, which has 17 miles of 30 inch iron pipe, conducting the water across depressions of from 200 to 250 feet vertical depth.

During the summer and fall of 1870 the most important enterprise of this kind was carried out by the Spring Valley Canal and Mining company, of Cherokee, Butte county.

Under the direction of Joseph Moore, Esq., Superintendent of the Risdon Iron and Boiler works in San Francisco, an iron pipe 30 inches in diameter and 14,000 feet long was manufactured and laid across a depression of nearly a

air. A stand-pipe is adjusted 50 feet from the inlet, to permit the ready flow of water and the escape of air which may have entered the pipe. The pipe is laid in pieces 23 feet in length, riveted together, and in a trench five feet deep, and covered with soil to save it from thermal influences, causing expansion and contraction. The rivets used were for No. 14 iron, one-fourth wire, for No. 12, one-fourth; for No. 11, three-sixteenths; for No. 9, three-eighths; for No. 7, three-eighths. A steam riveting machine was employed. Air-valves, with floats, are used at different places, not only to allow the escape of air, when the pipe is filled, but also to prevent a collapse from atmospheric pressure, in case a vacuum should be created by some foreign matter (for instance, a plug of dry leaves accumulated in the ditch) stopping suddenly the supply of water.

Condensed from an article by Charles Waldeyer, of the last Annual Report of the U. S. Commissioner of Mining Statistics.

The Virginia and Truckee railroad company carried in the month of January 19,747 tons of ore from the Comstock mines to the mills. This light shipment is due to the stormy weather in January, when the dumps of several mines became filled, and they were obliged to stop hoisting.

The Amador Ledger thinks the gold yield of the quartz mines in that county for 1875, will be greater than the product of any preceding year.

One day last week twenty twelve-mule teams were at Spadra, loading with freight for Panamint.

Improved Water Wheel.

Mr. S. N. Knight, of Sutter creek, California, has recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency, an improved form of bucket for use in hurdy-gurdy wheels. The invention also comprises an improved method of fastening buckets to the wheel, so as to materially increase the effectiveness of the wheel and reduce the cost of construction.

The accompanying cuts show the design in detail. Figure 1 is a perspective view of the invention, and Figure 2 is an enlarged view of some of the buckets. A represents the hub, B the spokes, and C, the felloe of a cast iron wheel. Around the rim C, of the wheel, are secured wrought iron or equivalent pressed, or forged buckets d, d, d. In this class of water wheels, the wheel is secured upon a horizontal shaft E, as that it rotates in a vertical plane; and the water is delivered upon the buckets by a nozzle F, which may be arranged to deliver the stream upon the buckets at any desired point in the circumference of the wheel rim. The comparative effectiveness of the wheel will, therefore, depend on the capacity of the buckets to utilize the force of the water as it leaves the nozzle; it being necessary that the buckets be not only capable of receiving the force of the entire stream, but also that they free themselves easily the moment the force of the water is expended.

The buckets d, d, d, are made of wrought iron, or they can be with forged or pressed into the desired shape. These buckets are made scoop-shaped, and the base of the scoop or outer side of each bucket which is farthest from the wheel rim, is cut out in a semi-circular form, as at i, so as to provide a sufficient opening for the entrance of the stream of water into the buckets, while the sides extend upward close to the bucket next above. These buckets are secured very close together, so that as the outer edge of each bucket commences to pass the stream from the nozzle, the water will strike into the next bucket. Each bucket is firmly secured to the rim of the wheel so that the bottom of the scoop will stand at an angle to the rim as shown.

The stream of water will strike into the buckets, and, in its reaction, will be discharged, thus giving the wheel an impetus which is not affected by "dead" water; and this action being continuous, on account of the arrangement of the buckets, the full force of the water will be expended to the greatest advantage. Parties desiring further information may confer with the inventor at the address given above.

Washington's Birthday.

The date of this week's PUES is close upon the heels of the anniversary of the birthday of America's greatest man. The eulogies on Washington have probably been as numerous as those that have been bestowed upon any man that the world has seen; and they will never cease; for the most brilliant eulogists will never fail to find something in his character or record to praise, and his more humble admirers will realize more and more the greatness and goodness of America's model man. Our indebtedness to Washington as a soldier and statesman has been duly acknowledged by the present and past generations; but it will not be until many generations have passed away that the nation fully realize its indebtedness to Heaven, through him, in furnishing us with a model which, lofty as it is, presents more incentive to popular imitation than any other hero of history; and in the character of Washington we see this important truth demonstrated, that greatness and goodness are not incompatible.

The recent caving of the Indian Valley (Plumas county) mining company's grounds near Greenville, closed up the chute and made it necessary to have a new one before operations could be carried on successfully.

MINING matters in the Reville District, Nev., are looking up. It is the intention of those interested in the mines there to have the mill running this spring.

CORRESPONDENCE.

The Sale of American Ores.

ENRORS PRESS:—In the interest of many of my acquaintances who send their ores to Swansea, London and Liverpool, and of American ore-shippers generally, I beg to call attention through the columns of your paper, to a few facts in connection therewith. As the result of personal observation I have ascertained that there exists a "private contract" system, by which many lots of auriferous and argentiferous ores are disposed of at rates, much below those which would be otherwise obtained, were the ores sold by public ticketing, and the sample fully and impartially distributed. Noticing that several lots had been disposed of rather quietly, I took occasion to compare what I afterward learned to be the prices paid with the rates offered by the Swansea agent of the Royal United Smelting Works of Germany (Mr. F. W. Dahne), and found that his prices would have netted the owners from \$30 to \$50 more per ton. As the tariff rates of these works seem to represent the maximum prices offered, I will mention in this connection that Mr. D. pays, in cash, the full tariff rates up to 1s. 11d. per oz. of silver, and 75s. per oz. of gold. I found, however, that three firms—Richardson & Co., and Elford, Williams & Co., of Swansea, and Lewie & Sons, of Liverpool—were honorable exceptions in the matter of this private contract system; but I would advise our ore shippers that if they expect fair prices they must make it a condition that the ores shall be sold by public ticketing, and that the printed circulars containing the lists of bidders should be sent to them so that they may see if the concerns paying the maximum prices are properly represented. We have heard a great deal about American windmills in connection with English mining matters, but the existing facts, as I have stated them, would seem to indicate that a counter charge might not be wholly unsustained.

NEVADA.

Petroleum in Russia.

The production and refining of petroleum, which, until recently, was almost exclusively an American industry, appears to be fast gaining a foothold in many other portions of the world. We made brief mention last week of the inception of this business in Germany; to-day we allude more fully to the enormous proportions which it is assuming in Southeastern Russia. Mineral oil is found in immense quantities near Baku, a city about midway of the eastern shore of the Caspian sea, and from which it can readily be shipped by water through the river Volga to near the center of European Russia. Some eighty refineries have already been established near the city of Baku, and systems of pipes are being laid down to convey the oil from the springs and wells to the refineries which are built along the sea shore. A large additional number of refineries have recently been projected. Steamers are being built especially for the traffic to carry oil in bulk, and railroads are in contemplation to connect with the general railway system of the Empire. It is altogether probable that Russia will soon become a large exporter of petroleum, and a rival of America in that business in European markets.

Description of the Oil Regions.

The interest which is beginning to attach to this locality makes opportune some description of its chief characteristics. Baku is located at the southeast end of the Caucasian mountains where they push out into the Caspian sea forming a peninsula or huge headland. The town, located at the foot of a steep declivity by the sea, is a very ancient one, and up to the inception of this new business contained a population of about 5,000 people. It is now rapidly increasing. Its business, heretofore, has been confined chiefly to raw silks, rich carpets, shawls, rice and naphtha. The peninsula upon which it is located is called Apsheron. It has always been celebrated for its mud volcanoes and naphtha springs. Near these springs is a locality known as "The Field of Fire," about half a square mile in extent, from which inflammable gas is constantly escaping. In ancient times this locality was held in the highest veneration by the Eastern fire worshippers and is even now frequented by great numbers of pilgrims every year. They have also several temples there at which some of the more rigid devotees spend most of their time in constant worship, and penitential exercises which often terminate the lives of the poor deluded wretches.

At one locality not far distant from this, there is a huge jet of inflammable gas escaping from the calcareous rocks, and constantly burning which is especially worshiped as representative of the divine principle of fire. This utilitarian spirit which has now so forcibly invaded the region, will probably lead to a gradual overthrow of the peculiar religious sentiment which has reigned here with so much intensity from the earliest period of recorded history.

Canadian Reciprocity—What it Means.

The pending treaty for reciprocity with Canada, it is suspected with much reason, is simply designed to make a way for the transfer of British capital to that province instead of to the United States, whether it must soon come direct, unless let in indirectly, through the back door, by way of Canada. It is proposed that the treaty shall continue for the term of twenty years. With the advantages of such a length of time Canada would become the workshop of England, where cheap labor could be utilized, with an abundant and free market just across the line. However injurious such a policy might prove to the industries and revenue of the United States, there would be no way of abrogating it short of the sword. Congress would be bound hand and foot, and sold to a British dependency for a term of years. Bearing none of the burdens of our debt, receiving the goods produced of our soil and mines, free of duty, employing the cheap labor of England, the Canadian manufacturer would enjoy such advantages as would utterly preclude all possibility of competition on the part of our own manufacturers.

If Canada desires to build up a better trade with the American Union let her come into it and help bear its burdens. Until she thinks fit to do this, let us endeavor, by a cheap, honest and stable government, a sound currency and cheap rate of interest, to so reduce the cost of living that our mechanics and manufacturers can furnish what we want as cheaply as can those of Great Britain. We can do all this if we will, without working any hardship to either our moneyed men or to our producing classes. Reciprocity with Canada means starvation at home. It might furnish a limited market for our breadstuffs there, but it would, by just so much, diminish our breadstuffs market at home. Free trade is certainly a most desirable end; but it would be a ruinous policy to adopt until we have put our own house in order.

The Champion Mine.

The Calaveras Citizen says: We visited recently the Champion mine at West Point, and as it is the mine they "swear by" up there, we thought it of interest to obtain the following particulars: It is located three-quarters of a mile northwest of the town, and is owned by Haskins and Hadley. They claim 1,500 feet and have applied for a patent. The ledge runs nearly north and south, and has been prospected and tested for the distance of 700 feet. This north and south vein varies from 18 inches to 3 feet in width, and where rock has been crushed, taken from the vein, it has averaged \$100 per ton. Where their working shaft is now located, at the depth of 75 feet, an east and west vein intersects the north and south vein; this cross vein had steadily lengthened as they went down, till now, at the depth of 140 feet, it has grown from mere nothing to 25 feet as tested, and how much further is to be determined. This cross vein will average something over one foot in thickness and pays from \$140 to \$200 per ton. The last rock crushed taken from both veins paid \$140 per ton, and it is claimed that the rock now being taken out will pay \$200 per ton; it looked to us as though it would pay \$2,000, for the dump is "yaller as saffron." The gold is distributed through the mass of the rock and not, as in many instances, confined to seams. It is a sulphuretted rock of a bluish cast, and Mr. Haskins informed us that a tea saucer full of sulphuretted, reduced by means of acids, yielded a teaspoonful of gold, this being the only test they have ever made. The mine is worked by means of water-power hoisting works, and the same power is employed in pumping the shaft from a tank built at the depth of 100 feet, where the most of the water is collected. The water, though, is no obstacle worth mentioning, as an hours pumping will keep the shaft dry for the day. We believe, from what we saw and what we were told, that this mine is equally as good as the far famed "Sheep Ranch mine," and it may be safely claimed that Calaveras has two "bonanzas" well developed, and better property, for the amount invested, than feet in the California Consolidated.

THE MARIPOSA ESTATE.—We are informed from a reliable source that the estate which was sold at sheriff's sale at Mariposa on the 26th of January last, to justify judgment against it amounting to the sum of \$66,667, and the title to be got at under it by an arrangement with the re-incorporated Mariposa Land and Mining company, the purchaser is to sell and transfer all to it. It is well understood that all incorporations are enabled, through their own resources by assessments where under the authority of California law, to provide and furnish means to protect, develop and make valuable their property, that this will really be the first real chance this much abused property has had since it was floated upon the New York market, with millions of stock and bonded debt—and outstanding titles to afford endless litigation; this is now arranged to be settled, and Mariposa will, we hope, assume a name and reputation which she deserved long since. We now see an end to all litigation, and the company being under California law, and under the jurisdiction as the estate, there can be no more conflicts used to depress and ruin all in interest as has been heretofore. It has been a terrible load for a few to carry, but the concern will now carry itself, and the system will be upon the cash principle—pay as they go.

—Calaveras Chronicle.

Work and Wages in California.

The following was compiled for the *Resources of California*, by a gentleman who is very thorough and painstaking, and we are able to vouch for the general correctness of his statements and figures. Herein is an infallible index to the industrial condition of the State:

Among the most vital questions to which the world-be-citizen of California early and rightly demands definite, reliable, and satisfactory answers, before taking as serious and important a life-step as that of breaking away from the associations of earlier life, and deciding to identify the fortunes of himself and family with those of the Golden State, those pertaining to work and wages naturally stand foremost in interest and uppermost in importance.

"Is there plenty of my kind of work in your city and your State? Is the demand for it permanent and steady? Are wages good? Is the pay sure? Is it prompt? In what do we receive our pay? What is the price of board? How are rents? What are the prices of provisions, of fuel and of clothing? How much will it cost me a month, or a year, to keep a family of two, of four, of six?" These and scores of kindred inquiries, closely connected with them or immediately growing out of them, form the chief burden of hundreds of letters, public and private, from individuals, families and companies, weekly addressed to private citizens, prominent officials and, especially, to ourselves.

They are wholly right and proper. No sane man, even if single—certainly no head of a family, in his right mind—unless, indeed, he be independently rich—could seriously contemplate an enterprise as important as that of wholly removing his earthly home, with all its memories, associations, and the myriad life-interests inseparably involved; certainly should never finally decide that most vital of life questions—without having fully collected, carefully balanced and deliberately considered all reliable evidence possibly obtainable.

To answer just such questions, and to provide others with the means of answering them; to furnish just such evidence in a form at once complete and compact, critically exact and thoroughly reliable in every particular, and, in point of recency, brought down to the very beginning of the new year—1875—is the especial purpose of this paper. To place in the hands, or within easy reach, of our numerous subscribers, as well as to furnish our own citizens with the readiest possible facilities for immediately returning full and authentic answers to these constantly increasing letters from eastern friends, we have for some months been contemplating, and, for several weeks, carefully collecting facts and comparing statistics in preparation for the present article, which we now confidently present as a recent, authentic and reliable; including all the essential facts personally obtained from original sources, and patiently prepared with the utmost care.

We have taken especial pains to get both sides of the case, in regard to every calling, where it was in any way practicable. We have not only asked the employer what he pays, but inquired of the employee what he gets. At first thought, this might seem superfluous. We have a habit of considering this a thing so simple that a single inquiry, and that upon only one side, had generally appeared quite sufficient. Unlikely as it may have been considered, however, it is, nevertheless, a simple fact that this balancing of inquiries has occasionally revealed quite considerable and even remarkable discrepancies. In more than one case the employer, as if anxious to gain credit for liberality, represented himself as paying higher wages than the unhesitatingly unanimous testimony of the employees assured us that they received. On the other hand, the employees in several instances understated their pay, as was subsequently proven by the concurrent testimony of their mates, and of themselves, even, when carefully and separately cross-questioned. In matters of this kind more than in almost any other interest of life, human vanity and human selfishness sometimes sadly interfere with the veracity and consequent reliability of human testimony. Hence, in attempting to ascertain the facts about any one calling, it frequently became necessary to visit and interview from five to ten different employers in various parts, not only of the city, but, also, of neighboring cities and even of the State at large, and to very carefully question and consider the evidence of from two to three times as many employees.

In the tabulated results hereto appended we have tried to show, as far as practicable the highest, the lowest, and especially the average wages paid to the different kinds, grades, or kinds of operatives employed in the various departments of each calling; to give the daily, weekly or monthly pay, according to the particular method or pe-

riod of payment, generally prevalent in that business, and to state the number of hours a day generally exacted.

In arranging those which we have selected, we have adopted the alphabetic order, as that which, upon the whole, obviously involves the fewest objections, and presents the greatest convenience.

ARCHITECTS.—Work as usual, either by special rate or by commission. The supply so fully equals the demand that their commissions or compensations but little exceed the ruling rates in the larger Eastern cities. The unprecedented activity in building, in which San Francisco has far surpassed herself, even during the last six months, has correspondingly increased the fees and wages of all artisans concerned in the erection, completion and furnishing of public or private buildings.

ARTISTS.—Are finding increased appreciation and obtaining proportionally better prices. Diversities of talent, genius, or reputation cause such an almost endless variety of reward that one can hardly venture upon even an approximate statement of average compensation. Painters of landscapes, marine views, theatrical scenery, panel work, etc., are in full force, and possess an unusual aggregate of talent. Retouchers and colorers of photographic obtain from \$3 to \$15 a day. Skilled workers in water-colors command fully as much.

BAKERS.—These workers of the staff of life receive from \$40 to \$60 a month, and board. Foremen get \$60 with board and lodging; in rare cases they command \$100, while in a few first-class hotels, or extra fashionable restaurants, the chief baker makes even \$250 a month. In ordinary bakeries, second hands have \$40, and third hands \$30, with board and lodging in both cases.

BARBERS.—Good journeymen barbers may depend upon an average pay of from \$15 to \$20 a week, without board. The usual wages, in the cities and larger towns, range from \$15 to \$25, depending, of course, upon the skill of the workman and the amount of custom which the establishment enjoys.

BLACKSMITHS.—Readily command from \$3 to \$4 a day, and generally work ten hours a day. In the mines they receive an average of \$60 a month, without board. Foremen get from one-fifth to one-fourth more.

BOAT-BUILDERS.—Work ten hours a day for \$3. This business employs hardly a hundred men in all, but they turn out excellent work and are steadily increasing in numbers.

BOILER-MAKERS.—command \$3.75 a day; generally working ten hours. *Flange Turners* receive \$4.

BOOK-BINDERS.—May depend upon from \$2.50 to \$5 a day; boys from \$3.50 to \$12 a week.

BOOK-KEEPERS.—All the way from \$60 to \$200 a month. In some banking houses or large importing or commission houses, book-keepers receive from \$250 to \$300 a month, but these are so rare as not to affect the general average—which we may safely set at \$125 a month.

BOX-MAKERS.—\$2.50 a day, for ten hours, upon either paper or wooden boxes.

BRICKLAYERS.—From \$4 to \$5. Foremen, \$6 to \$8.

BUTCHERS.—\$40 to \$75; average, \$50 a month.

CABINET-MAKERS.—Average \$4 a day. More than half of those employed in the city work by the piece, in which, of course, their earnings depend directly upon their own skill and dispatch.

CARPENTERS.—House-carpenters command \$3.50; foremen from \$4.50 to \$6. Ship carpenters or joiners, \$4.50; foremen, from \$5 to \$7.50.

CARRIAGE-MAKERS.—Body-makers and wheel-wrights average \$3; trimmers, \$4 painters, \$2.50 to \$3; strippers, \$4.

CARTERS.—\$2, when the employer furnishes the team; when they furnish and keep their own horse and cart, they get from \$3.50 to \$4.

CARVERS.—In wood easily command \$3.50 a day; when they work by the piece and upon fine work, some make as high as \$7.50 or even \$8.

CAULKERS.—\$5 a day for nine hours and a half.

CHAMBERMAINS.—In families average \$2 a month and board; in hotels, from \$25 to \$30.

CIGAR-MAKERS.—Are nearly all Chinese men. They get 90 cents a day; some as low as 75 cents, and even 50 cents.

CLERGYMEN.—Receive all salaries from one to seven or eight thousand dollars a year. Taking city and country together the average salary is not far from \$1,500. That of San Francisco is about \$2,300.

CLERKS.—No calling includes greater diversity of talent and occupation, and consequent inequality of compensation. Wage range from 75 cents a day, for good boys; writing a good hand, possessing fair knowledge of business computation, and hav-

(Continued on Page 116.)

MECHANICAL PROGRESS

Rollway vs. Railway.

Another Single Track Railway Device.

A highly interesting paper was recently submitted to the Civil Engineer's Club, of Chicago, by S. A. Clemens, on the substitution of a roll way for the railway system now employed on the great thoroughfares of the country. The novelty of the idea will attract the attention of all railway mechanics, and the question of its possibility will no doubt awaken much discussion. As described in the *Railway World*, this new device appears to be a modification of the single track railway, which has of late attracted so much attention in this city. The roadway consists of a series of pairs of small wheels or rollers, each supported by journal boxes, or equivalents, bolted to timbers, like railroad ties, which are placed side by side and set fast in the ground. The way-rollers of each pair are placed parallel—from three to five feet apart, according to any determined gauge—and the pairs of rollers may be eight to sixteen feet apart on the line. Midway between the rollers thus arranged in two parallel rows, is a single guide-rail, the top of which is three or four inches above the level of the rollers, and its connected sections are strongly fastened to the ground timbers to which the rollers are secured, thus tying the entire superstructure longitudinally together.

The way-rollers, made of chilled iron, or converted steel castings, are of about five inches diameter, with three-inch faces, and have on each side journals of two and a half inches in diameter and length, which revolve on small steel, anti-friction rollers, in chilled iron journal boxes, so closed as to exclude both dust and rain. Or, preferably, the way-rollers may be steel or wrought-iron tubes about five inches long by four inches outside diameter, and five-eighths of an inch thick, revolving on steel, anti-friction rollers, of about three-eighths of an inch diameter, which encircle and roll around a short fixed steel shaft, two inches in diameter, the ends of which are held in supports of hard wood or iron, bolted to the ground timbers. These tubular way-rollers are designed of three-fold capacity to safely endure the train weights at highest speed to which they are to be subjected, while combining low resistance from friction and inertia. For the purpose of obtaining favorable grades and curves, the ground-line is prepared like the ordinary road-bed, with the exception that the grade is not necessarily required to be continuous.

The cars are to be from thirty to fifty feet in length, with timber-runners shod with steel, and elastic rubber cushions to run over the rollers, while a system of guide rollers provided with flanges run along the central or guide rail, to keep the cars from flying the track. The outside rollers are placed at intervals, so that the runners of the car overlap at least three of them at the same time, while they may be laced closer together if it is found to be desirable.

The locomotives have an under construction similar to the cars, with steel shod runners upon the outer lines of rollers, and secured to the central or guide rail by flanged rollers. The driving wheels of the locomotive are horizontal, in pairs, and bear on opposite sides of the double-headed guide-rail. Adjustable pressure for tractive adhesion of the driving-wheels on the guide-rail is obtained by spring-cushioned screw or eccentric rolling pressure, at the control of the engineer.

The rollway car-brakes are arranged to act directly on opposite sides of the guide rail, and they may be made on any operating principle now approved by railway usage. At road crossings, a section of the two-guide rail is left out, and the space between adjacent pairs of the way-rollers is open and unobstructed. This is made practicable by providing flanges on two or three pairs of the way rollers on each side of the crossing, to guide the car-runners in straight lines over the crossing, on the further side of which the driving-wheels and guide-rollers again come into position.

But how about switching this style of cars and locomotives? The inventor has provided for this by having a section of guide-rail on the line, which being pivoted at one end is swung outward at the opposite end, to meet in line with an outside section of switch guide-rail which is swung inwardly, both moving simultaneously, by mutual connection to the same switch-lever.

This very general description of the new roadway presents a problem in engineering which is probably worth more than a passing consideration. For underground and elevated lines of transit the system is especially urged for its cheapness and security. It is claimed that the cost of constructing the rollway is from one-half to two-thirds less than the ordinary railway, while the cost of equipment is proportionally smaller.

STEAM TOWAGE ON CANALS.—According to the *Moniteur Industriel Belge*, a system of steam towage is about to be established on the Bourgoigne canal, over a distance of about 150 miles. The tow path will be laid with a single rail weighing some 16 lbs. to the yard, and fixed on reverse placed 3 1/2 ft. apart. The locomotive has four wheels, two of which are placed di-

rectly along the axis of the vehicle, one in advance of the other, and two, one at either side. The former pair are directing, the latter driving wheels. The directing wheels are grooved, and fit the rail; the others have rubber tires which give purchase on the macadamised road, and which press thereon only to the extent of 0.07 lb. per square inch. By means of simple mechanism, the weight of the machine may be thrown either upon the driving or directing wheels at will. In the first case the maximum and in the last the minimum of adhesion is obtained, to suit the conditions of a loaded or an empty boat. A single road is to be used, with r-lay engines provided at suitable distances. Each locomotive tows one boat; and when a meeting takes place of two travelling in opposite directions, the engines change boats and retrace their paths. This single rail system has already been satisfactorily tested for short distances on the Belgian canals, and the projector, M. Larmangat, has obtained a Government concession for its extended construction for forty years. The locomotives are to weigh four tons each, and will travel at the rate of 3.1 miles per hour, with full boats carrying a cargo of 150 tons each.

COMPETITIVE PROPELLERS.—A recently published report of comparative tests, made by the English line of steamers, between the Hirsch and the Griffiths propellers, shows, says the *Scientific American*, a strong preponderance of advantages in favor of the screws of the former system. The steamship "Herder," was fitted with a Hirsch screw, built for an increased speed and also with a Griffiths propeller. The mean results of ten voyages between Hamburg and New York show for the Griffiths a speed 11.59 knots; time under steam, 10 days, 17 hours, 30 minutes; coal consumed on passage, 572 tons; and 519.05 miles run on 100 tons of coal. For the Hirsch, 13 knots; 9 days and 13 hours; 505 tons and 582.79 miles; a gain of 12 knots per hour, and an economy of 67 tons of coal. The Goethe, of the same line, the engines of which, like those of the Herder, are of 600 horse power nominal, was fitted with a Hirsch screw designed for saving coal. The saving effected was four tons per 24 hours, and this, although the draught of the vessel was one foot seven inches more than when the Griffiths screw was in place. On board the Leasing, another vessel belonging to the same company, the Hirsch propeller caused a gain of 14.7 per cent. in speed. The official reports of the engineers state that the engines driving the Hirsch screw worked exceedingly smoothly, and that there was a noticeable absence of any vibration.

AN IMPROVED FREIGHT CAR.—The expense of hauling so large a proportion of dead weight to the paying load, as is now carried on railroads, has of late years attracted a great deal of attention, and has been the subject of much discussion among railroad managers. Many of our readers will, therefore, be interested in the reported fact that Mr. Richard Eaton, late master of motive power of the Grand Trunk railroad, has devised a car of much less weight than those generally in use, but with the strength and capacity for carrying about one-third more weight.

If this object is attained, the advantages which will result therefrom are, of course, very great. The usual load for ordinary cars is 20,000 pounds, their weight being about the same. A train of 30 cars will, therefore, carry 600,000 pounds of freight. The cars will be of about equal weight, and, with that of the locomotive, the total weight of the train will be 1,300,000 pounds. A train of the improved cars, of equal weight, would consist of 20 such loaded cars. They will, however, each carry 40,000 pounds of freight, or a total of 800,000 pounds, or one-third more than the other train. Three trains of the improved cars will, therefore, transport as much freight as four with ordinary cars. The saving resulting therefrom is, of course, very apparent. These cars are especially intended for the grain traffic of the East and West roads, and their use, it is claimed, will reduce the cost of transportation very materially.

EFFECT OF FROST ON RAILROADING.—Many experiments, says *Nature*, have been tried in France to test the effects of cold on railway axles. Many engineers suppose that accidents to wheels do not result from any diminution of tenacity of the metal, but merely from the road losing all its elasticity owing to the frost hardening the surface of the earth. A fact which can be adduced as a strong argument in favor of that theory was observed by the inhabitants of Montmartre during the last period of frost. The passing of the trains which run so frequently through the Batignolles tunnel at a distance of half a mile, was heard by them day and night, which is never the case in ordinary circumstances. As soon as the thaw set in the trains ceased to be heard; the earth having resumed its former elasticity, the sounds were dissipated as before. It has been observed by French railway engineers that thaws are apt to lead to the breaking of axles and chains. The elasticity being only partially recovered, many shocks affect the trains when running at a fast rate, and are apt to lead to catastrophes.

BLAST FURNACE PROGRESS IN THE NORTH OF ENGLAND.—Notwithstanding that there has been no increase in the production of either iron ore, pig iron, or finished iron, still the smelting capabilities of the north of England have during 1874 made substantial progress, by the erection of twelve new blast furnaces in that region. This will give a possible yield of at least 200,000 tons in excess of twelve months ago.

SCIENTIFIC PROGRESS.

The Future of Telegraphy.

The improvements which have been made during the past five years upon the Morse system of telegraphing are but little less wonderful than the original invention. Ten years ago any operator would have considered a piece of absurd folly the notion that two messages going in opposite directions could be simultaneously sent upon one wire, but the Stearns' instruments have not only succeeded in accomplishing this, but they have also made it possible to use one wire to send four messages at the same moment.

The duplex instrument was followed by the quadruplex, and it is now only a question whether the capacities of a single wire cannot be further multiplied. Mr. Stearns' inventions were simply extensions of the Morse system, and in the view of many practical electricians there are other systems which will prove to be of far greater advantage than it. The automatic telegraph is yet crude, and presents several opportunities for improvement, but it cannot be doubted that with the addition of certain mechanical aids it would approach nearly to the perfection of cheap and rapid telegraphy. The competition between the Morse and the automatic system is developing both, and as successive discoveries increase the speed and diminish the cost of transmission, we approach the period when the telegraph shall be as facile a servant of the public as the mails now are.

All these inventions tend to secure the great object of cheap telegraphing. By the use of the improved methods that are now being worked up the cost of the transmission of messages can be reduced to something near the *pro rata* charged in England, where the telegraph is made a department of the Government, and the tariff placed at a rate above the actual cost. To this end the need of men of large practical experience is most necessary, and it is a matter of no small interest in this direction that Col. Eckert has recently resigned his position in the employ of the Western Union Telegraph to devote his time exclusively to working out to its fullest extent the problem of cheap telegraphy.

The progress of telegraphy in England is far behind what has been achieved in this country. Their systems are so slow and inefficient, as compared with the more advanced systems employed on this side of the Atlantic, that it is claimed our companies may reduce their tariffs to the cost price in England and still realize a profit which shall afford a fair interest on their investments.

AN EXTRAORDINARY CHANGE IN TEMPERATURE.

A correspondent of the *Germantown Telegraph* writes to that journal as follows:

I had an extraordinary experience on the 8th and wish to relate it to you. The morning was cloudy and the temperature mild and pleasant—suitable to go to the interior, one mile and a half distant for firewood. While on the way down to the woods snow commenced falling, the wind being from the south, and continued to snow until within one mile of my home on my way back with the load of wood, when all of a sudden, the wind shifted to the northwest with a perfect fury of snow, cold and dust from the dry roads and fields. The scene was a fearful and an interesting one, and having read of a similar change somewhere in Nebraska, winter before last, I could not but query about my own prospective fate, "am I to perish here from cold when only a mile from home?" The thick clothing seemed to be of no more account than one thickness of linen.

Well, I succeeded in getting home, it was about 11 o'clock, a. m. and the mercury in the thermometer at zero. Before the change of the wind it was at about 30 degrees, and the fall of the mercury was 30 degrees while I was traveling one mile. There was no stoppage on the way and the horses quickened their walk, seeming to be as anxious to get home as I was. Allowing 25 minutes for my traveling one mile, on a good road, the mercury sunk 30 degrees in 25 minutes—a little more than one degree to each minute. The range of the mercury after 11 o'clock was as follows: 12.2 degrees below zero; 1.5 degrees below zero; 3.8 degrees below zero; 4.10 degrees below zero; 5.12 degrees below zero next morning at 6, 20 degrees below zero, and shortly after began to rise, but kept below zero all the time until to-day, the 10th, when at 9 o'clock it got above, and thus has ended an experience such as people in the Atlantic States never see, and only now and then that we do.

[The sudden change in temperature noticed was, no doubt, the result of a sudden down pour of snow from a great height in the atmosphere. —ENS. PRESS.]

DIFFUSIBILITY OF ODORS.—A curious fact, well worthy of attention, is the remarkable diffusibility and degree of subdivision exhibited by some odorous substances. Ambergis just thrown up on the shore spreads a fragrance to a very great distance, which guides the seekers after that precious substance. Springs of petroleum oil are scented at a very considerable distance. Bartholin affirms that the odor of rosmery at sea renders the shores of Spain distinguishable long before they are in sight. So, too, every one knows that a single grain of muck perfumes a room for a whole year, without sensibly losing weight. Haller relates that he has kept papers for forty years perfumed by a

grain of amber, and they still retained the fragrance at the end of that time. He remarks that every inch of their surface has been impregnated by 1-2,691,064,007 of one grain of amber, and that they had perfumed for 11,600 days a film of air at least a foot in thickness. Evidently the material quantity of the odorous principle contained in a given volume of such air is so minute as to elude imagination. We can readily conceive how philosophers cite such instances to give a notion of the divisibility of matter.—*Popular Science Monthly*.

PROGRESS OF CHEMICAL SCIENCE.—Where is the chemist who, living 50 years ago, would have believed that, taking for a starting point the elements of water, air, carbonic acid, azote and oxygen, it would have been possible to compose substances which have nothing analogous in mineral chemistry, such as the odorous principles of fruits; the irritating essences of garlic and mustard; the waxy matters known under the names of Chinese wax, and that of whals and bees; alkaloïds, similar to morphine, quinine, nicotine; the sweet scent of mint; and essence such as camphor; of cinnamon, cummin, aniseed; the acids of ants, of vinegar, butter, valerian, benzoin, sour milk and sorrel; the azotic matter contained in the bile. All these and many more, the chemist creates at his will. If he cannot fix in his retorts the vital principle, he can compose the necessary materials for a living being, and form as he pleases, a new world of immediate principles which are not met with in any known organisms. Thus the domain of organic chemistry grows wider as the functions of these composite types become better known; and yet, after gaining such a high, more extended horizon spread before it, new worlds await the bold explorer, and it is scarcely possible to assign a limit to its progress.—*Chamber's Journal*.

A CONSTANT ELECTRIC LIGHT.—A new and intensely white light has recently been invented and exhibited by Mr. William Dwyer, of Ohio. A thin ribbon of carbon is suspended between two platinum poles and covered by a glass containing dry carbonic acid gas. The ribbon receives an electric current from a battery, and while in the atmosphere of the gas becomes brilliantly incandescent. The carbon is not consumed, and the light is said to be perfectly constant. The method was invented by Prof. Osborn, of Miami University, who at first thought it necessary to use very thin strips of carbon, but the light is now produced with much larger ribbons and with little combustion. The heat generated has never as yet broken the small glass globe containing the ribbons. This light being constant, and not requiring the combustion of carbon, may prove much more useful to scientific lecturers than the ordinary electric or oxyhydrogen lights, both of which are troublesome to handle. The electric light which is so intense and so cheap, when it is produced by motion transformed into electricity by means of magnets, has not yet said its last word; on the contrary, it is still in its infancy. In the end it will no doubt be used all over the world for illuminating lighthouses, ships and workshops, nor must the immense services rendered by electricity during the siege of Paris be forgotten.

IMPORTANT AND INTERESTING TO GOLD ASSAYERS.—Mr. Dillon, the assayer to the Japanese Imperial mint at Osaka, in his report, says: I have very rarely detected iridium during the assay of the fine gold received for coinage, and never in the coins themselves. In the assay of sweep ingots from the melting room, however, it is invariably present in the cornet in such large quantities as to invalidate the accuracy of the assay. I have a piece of gold from the bottom of a pot where the iridium alloy is scattered through the metal in steel-colored crystalline grains of great hardness. As the arrangements of the refinery do not allow of the treatment I proposed for separating the iridium, my only plan has been to distribute the gold of the sweep ingots among several pots, when the iridium appears to alloy with the excess of gold; at least I have never succeeded in detecting any in the resulting bars or coins.

THE ENGLISH CHANNEL TUNNEL appears to be fast assuming shape for the early inception of the enterprise. It has evidently received a new impetus from the late visit of the Lord Mayor of London to Paris, and it is now hoped by the friends of the enterprise on both sides that the work will soon commence. It is estimated that the tunnel can be made in four years, for a million sterling (?) at the outside, and probably in less time and for less money. Experimental operations are to be commenced immediately. A shaft is to be sunk on each coast one hundred and fifty yards deep, and driven thence under the sea in ordinary drifting for a mile and a half, with a downward inclination. These driftings could afterward form the beginning of the tunnel at each end, so that at no very distant day a trip from London to Paris may be contemplated without the horror of "crossing the channel," so long the terror of the timid tourist.

WATER IN GLUE.—Some recently carefully conducted investigations have developed the unexpected fact that 16 to 18 per cent. of water may be obtained from the best of ordinary sheet glue. The presence of so much water was quite unexpected; and the quantity is nearly the same in fresh and in seasoned specimens, it is not a make-weight, although steam is very freely used in the rooms where glue is picked by the manufacturers.

Important to Inventors.—A Correct Decision.

It has heretofore been the practice of the Patent Office to reject applications for patents on former rejected cases. This has always appeared to me to be wrong, because a rejected application is not a live reference. If a first applicant did not see fit to prosecute his case after it was rejected by the office, or introduce his invention to the public, it ought to be considered as an abandoned invention as much so as when a person invents something and fails to make application for a patent within a specified time; and a subsequent and more diligent inventor steps in and secures the patent. In the latter instance the law upholds the diligent man, but in the former it rejects him. Many valuable inventions have been lost to the world, simply because the inventor became discouraged by a rejection, and failed to prosecute his case; and his rejected case would then stand as a bar to every subsequent applicant. Thus the world is deprived of the invention because no one would take the trouble to manufacture what every body else has as much right to make as himself. This rule of the Patent Office has been abandoned and rejected. Cases will not, hereafter, prevent inventors from securing their patents. We append the decision of the Commissioner of Patents in which this "new departure" is taken.

In the matter of the application of George L. Rouse and M. W. Stoddard, for a patent for an alleged "Improvement in Whisls," filed May 18th, 1874.

Appeal From the Examiners-in-Chief.

Two claims are left in the application which the Examiner rejects for want of novelty, citing as reference the patent of P. Murphy, August 12, 1873, and this application of Charles Spofford, filed August 2, 1871, and rejected the 8th day of the same month. The Examiner-in-Chief has affirmed the decision of the Examiner below, on the ground that the patent of Murphy is a good and sufficient answer to the claims of applicants. They have not discussed the pertinency of the rejected application of Spofford, as a reference.

After a careful examination, I have come to the conclusion that the Murphy patent is not a sufficient answer to the claims of Rouse and Stoddard, which are limited to the special construction shown and described by them. It is admitted, however, that this construction of wheel hubs shown and described in the application of Spofford is almost identically the same as that of appellants. More than two years having elapsed since the final rejection of Spofford's claim, his application is regarded as abandoned under the 32d section of the Patent Act.

It is insisted on the part of applicants that, in view of the recent decisions of the courts, a rejected and abandoned application does not constitute a bar to the grant of the patent sought by them. It becomes necessary, therefore, to examine this question and determine the practice of the office in view of the decisions referred to.

Within a few years, several decisions have been rendered in the United States Circuit Court, in which the effect on patents of prior rejected applications has been discussed; but the question did not receive the attention of the Supreme Court, until the case of Brown vs. Guild came up on appeal during the October term of 1873. One of the defenses set up against the Brown patent was an old application filed by Remy and Kelly in June, 1850, which was rejected and withdrawn the August following. The evidence showed that only one machine was ever made by them, and this merely for experiment in the year 1849. In discussing the effect of this application on the validity of Brown's patent, the Court uses the following language:

"The experiment made in 1849, when Remy worked it by hand, was a mere experiment, which was never repeated. It may have presented one or two ideas in advance of other machines, but it can hardly be said to anticipate the machine which we have described as Brown's. Were it not for the application for a patent it would justly be regarded as an abandoned experiment, incapable of being set up against any other claim. Can the fact that such an application was made and afterward voluntarily withdrawn, and never renewed, make any difference? We think not. Had a patent been actually granted to Remy and Kelly, it would have been different. The case would then have come directly within the seventh section of the act of 1836, which makes a 'patent,' or a 'description in a printed publication' of the invention claimed, a bar to a further patent therefor. But a mere application for a patent is not mentioned as such a bar. It can only have a bearing on the question of prior invention or discovery. If, upon the whole of the evidence, it appears that the alleged prior invention or discovery was only an experiment, and was never perfected or brought into actual use, but was abandoned and never revived by the alleged inventor, the mere fact of having unsuccessfully applied for a patent therefor cannot take the case out of the category of unsuccessful experiments." Brown vs. Guild, 6 Off. Gaz., 392.

There can be no mistake as to the meaning of this language; the doctrine is distinctly enunciated that a mere application is not a legal bar to the grant of a patent to a subsequent applicant. This decision must be heeded by the

Commissioner of Patents, and govern him in regulating the practice of the office. I have had frequent occasion to state my views on the necessity of harmony between the practice of the Patent Office and the rulings of the Courts. There can be no question about the propriety of this course. The Commissioner ought not either to issue patents which the courts will declare invalid, or to refuse the grant on grounds which have already been considered judicially and declared insufficient. But it will be noticed that the Supreme Court does not entirely ignore abandoned applications, for it is stated that they have a bearing on the 'question of prior invention or discovery,' and the effect of the application is made to depend on the question of actual use of the invention described therein.

It has been urged in argument that if no objection appears to the grant sought by Rouse and Stoddard, except the abandoned application of Spofford, the Commissioner should issue the patent and allow the question of public use to be determined hereafter in the courts. The suggestion must have its origin in a misconception of the duty of the Commissioner of Patents. The law makes him something more than a mere ministerial officer, whose function is to issue letters patent simply for the asking. The Commissioner is made the guardian not only of the rights of inventors, but also of the interests of the public. It is just as solemnly his duty to refuse to issue a patent which clearly ought not to be granted, as to grant the issue when the applicant shows an unimpeached right to the invention.

In this case, if without further inquiry the Commissioner should issue a patent to Rouse and Stoddard, and it should afterwards appear that the invention of Spofford was put into

public use, it would be invalid, as I understand the decision which has been quoted. It is his duty, therefore, to inform himself on this question, if possible, and the application of Spofford indicates the direction in which inquiry may be made. The only question in my mind is how to prosecute the investigation. The law restricts interferences to unexpired patents and pending applications. An interference, therefore, cannot be declared with an abandoned application. I have no doubt whatever, however, that the Commissioner of Patents has ample authority to institute an *ex parte* inquiry at any time, for the purpose of determining whether or not a statutory bar exists to the grant of a patent for which application is pending. This is necessary to enable him to comply with the statute. Unsatisfactory as *ex parte* evidence may be, it appears to be the only source of information open to the Commissioner in cases like the present, without further legislation, and I do not believe that in a single instance a patent should issue for an invention shown in a prior abandoned application without an attempt, at least, to settle the question of public use.

The decision of the Examiner-in-Chief, affirming the Examiner on reference to the patent of Murphy, is reversed. The application of Rouse and Stoddard is remanded to the Examiner, who is instructed to forthwith dispatch letters of inquiry to the applicant Spofford, and to his attorney or record, for the purpose of ascertaining whether the invention of the former has been brought into actual use. At the same time they will be informed that an application is now pending for the same invention, and that the inquiry is made for the purpose of determining the right of subsequent applicants to a patent therefor. Information furnished

by them should be in the form of affidavit, clearly and fully setting forth the facts in the case. Counter affidavit will also be received from applicants if they so desire. The issue of a patent will be determined by the information thus received.

Until otherwise ordered, this will be the rule and practice in the Patent Office in like cases.
J. M. THACHER,
Commissioner of Patents.

Ex. A. E. B., Jan. 28, 1875.

Mining Stocks.

The mining stock market still continues in a depressed condition; prices being low. Transactions for the past week have been few compared with the usual business of the Board. The news from the bonanza mines continues good, and a few years ago news like that now received, would send stocks to "top shelf" prices. Now, however, the atonement is so great that hardly anything can insure a rise. Everybody seems to be waiting for prices to touch bottom so that they can all get in before a rise. Some very heavy sales of Consolidated Virginia were made this week, which caused a temporary excitement. The strike in Woodville and the rise in Searge helped to enliven things a little, but the market generally has been dull.

Sales at the S. F. Stock Exchange.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALPINE COUNTY.

GLOBE.—Alpine *Chronicle*, February 6: Good progress is being made in the tunnel of this mine, running on the banging wall of the vein. The vein carries a large amount of iron pyrites and some yellow copper. This week a cross-cut through the vein was commenced, and, as the vein is large and the indications good, pay ore may be expected at any day.

AMADOR COUNTY.

THE MILLS AT SUTTER CREEK.—Amsdor *Ledger*, February 13: We learn that the mills at Sutter creek are grinding out their usual grists of gold, and the mines at Amsdor City still keep up their former gold reputation. The Phoenix at Plymouth, is steadily turning out its treasures, and has long ranked as one of the most valuable mines in the county. The last accounts from the Alpine represents the ore as being of an excellent quality, and that the mine improves as work progresses.

MINING ITEMS.—Pleasant gravel claims in the vicinity of Jackson and Sutter creek, are still attracting attention, and active preparations are making for mining on a number of them on an extensive scale. The gravel in Downs & Co.'s claim is looking very well, and gives a fine prospect to the pan, at points far above the bed-rock. A heavy blast of powder will be let off in the mine to-day, which, it is calculated, will upheave an immense amount of gravel.

AMADOR QUICKSILVER MINE.—The reduction works of the above named mine has been completed and is now being thoroughly dried. We learn the retort will be charged with ore on Monday next and then a practical test will be had of the value of the rock, and the fact established that the Amador mine will, in a short time, have quicksilver from its reduction works in the market. The ore from this mine is remarkably rich.

BUTTE COUNTY.

MINING ITEMS.—Oroville *Mercury*, Feb. 12: We are satisfied now that there was some truth in the rumor that the Cherokee mines were not likely to prove a failure. Our belief arises from seeing some little nuggets of gold from the mines left on the counter of Ridout, Smith & Co., for shipment to San Francisco. The little ohunks have a stamped value of \$62,000, and the Superintendent of the mine, Mr. Gregory, says they had to work twenty-five days to get it.

The Thompson's Flat of an early day has passed away. Although there may be good mining ground left, still but few attempt to get a living by that method. The most of the houses have been taken down and put up again on ranches, and are now the homes of farmers. Nearly all the land in the vicinity has been entered for agricultural purposes.

CALAVERAS COUNTY.

HYDRAULICING.—Calaveras *Chronicle*, Feb. 13: Very favorable progress is being made in opening and developing the great hydraulic claim in Happy valley, owned by George Emerson. The flume, a mile in length, is now laid, and the cutting of the ground-slucice through solid bed-rock, to reach the lowest point in the mine, is nearly completed. Quite an area of surface and a large quantity of tailings have been washed away, and new ground that prospects handsomely is being uncovered. The work of opening the mine has been tedious and expensive, but it has been done in a most thorough manner. A large force of hands is at present employed. All the appliances of the mine are first-class, and when fairly opened it will rank among the most extensive mining operations in the county.

WEST POINT ITEMS.—Forty tons of ore from Miller & Co's mine yielded \$28 per ton. The ore is slightly rebellious.

At the Mina Rica four men extracted about twelve tons of ore per day. The daily yield can be increased to fifty tons per twenty-four hours if necessary. The Superintendent recently let a contract to run a tunnel to tap the quartz vein formerly owned by San Francisco parties.

The Good Faith tunnel, the most substantial enterprise in the district, is in 200 ft.

Wickman & Co. have found good pay ore near the Pascoe mine.

The main shaft of the Boston is down 90 ft, showing an eighteen-inch vein worth \$25 per ton.

The Josephine shows now ten ft wide, about five ft of this being solid ore. The mine will probably change hands in a very short time.

Some 70 tons of croppings and float, obtained at the Woodhouse, and valued at \$40 per ton, is being crushed at Harris' mill.

The Big Flat mine continues to yield ore which shows more gold than any other produced in this State. The chimney is slightly lengthening and somewhat wider.

The Onetom mills are running at full capacity.

A LARGE number of small mines are being vigorously attacked since the fine weather set in.

COLUSA COUNTY.

SILVER.—Colusa *Sun*, Feb. 13: There is considerable excitement out on the mountains over the discovery of an immense body of ore, supposed to be silver. J. W. Brim, of Bear val-

ley, discovered the body of ore eleven years ago, but, like all old miners, he did not suppose there was "anything valuable in the Coast Range!" He concluded, however, last week, that he would go out and take a look at it, and locate it "rough at a venture." He brought in some of the ore and with a blacksmith's forge run out a quantity of some kind of white metal exactly like silver, but whether it is all or any portion silver, we have not, up to going to press, been able to determine. If the metal he gets is silver, it will go many thousands of dollars to the ton. The mine discovered some time ago by Mr. Gaither, of Indian valley, assays some ten or twelve dollars to the ton in silver, and gets richer as they go down on it.

EL DORADO COUNTY.

GUKENWOOD AND GEORGETOWN.—Cor. *Mountain Democrat* (Placerville), Feb. 13: At the International mine operations are being pushed with energy, all the men being employed for whom they can find accommodations. Fine reduction works are to be erected immediately. Operations have been commenced on the Five Cent Hill mine, with a fair prospect of success.

From the famous Woodside mine, at Georgetown, come reports that the ore continues very rich. A large amount of gold will doubtless be taken from this mine within the next thirty days.

The Taylor mine is in course of successful development under the management of Walter Schmidt, the battery crushing fifteen tons a day and is never idle. About twenty men are employed at this mine at present.

The Garded valley mine has reached a depth of about 50 ft, showing a ledge of from four to six ft in width, that prospects splendidly in fine gold disseminated all through the ledge.

KERN COUNTY.

SUMNER MINE.—Kern County *Courier*, Feb. 13: Mr. Nelson, of Kernville informs us that the new hoisting works of the Sumner mine work admirably. They were not long in clearing the mine of water. A large force are engaged taking out rock. The mill will be started in six weeks. The town is growing rapidly. Lots sell at high figures, and efforts are being made to straighten up the irregularities of early times, that occurred before the great future of the place was foreseen, by conforming to a regular survey.

NAPA COUNTY.

MINING ITEMS.—St. Helena *Star*, February 11: Dr. Michel and Mr. J. J. Dickinson are in full blast on their copper ledge in Moore cañon. They are now running a tunnel in on the ledge and expect within two days to make a good showing. The last assay of their ore (made at University of California) gave \$3.50 gold, \$12.50 silver, and \$82.50 in copper.

There is a company being formed to work the Alum mine east of this place, mention of which we made last week, as having been discovered by Messrs. Hull and Bryant. The ore is fully 50 per cent., and they have hopes of striking it much richer, by going in on the bluff, where it crops out.

Mr. John Walton has, within the last week, located two deposits of chrome iron. One near the town of Calistoga, and the other near the Adobe in Chiles' cañon.

ITEMS.—Napa *Reporter*, February 13: During the storm a number of the mines had to suspend work on account of surface water, and in many instances considerable damage has been done, and it will require time and labor to put them in working condition. Of late there has been an unusual amount of activity shown in many stocks, some very important sales have been made of mines to capitalists who are making extensive preparations to work these claims in a thorough business like manner.

Capital is what we want amongst us. We have the mines, but it requires money to develop them. Pine Flat and vicinity next spring will present a lively front for many operations. The Cressus mine, near the Little Geysers, has been sold for \$200,000. The purchasers are Messrs. Carr and Ralston. It is their intention to put up extensive works for reducing their ores. This mine is considered one of the richest in Cinnabar district.

NEVADA COUNTY.

MURCHIE MINES.—Nevada *Transcript*, February 10: The mines owned by the Murchie's are all being worked to their fullest capacity and are looking first-rate. Rich rock is being taken out of the two quartz ledges, and the gravel in the hydraulic claim prospects splendidly. Hoisting works have not yet been erected at the Lone Star, but it will be done some time soon.

GOLD RUN MINE.—We took a walk yesterday out to the Gold Run mine, on Gold Flat. We found everything working in first class order. The company have put up heavy machinery of the best kind, and it is running as smoothly as it is possible to do. The incline is now down 250 ft, and drifts are being run both ways from the shaft. The ledge is eighteen inches thick and is looking pretty well. The rock is being hauled to Jones & Keith's mill to be crushed. There are eight men at work underground at Gold Run, and more will doubtless be put on as room is made for them. Superintendent Montgomery works everything to advantage around the mine, and expects, when he gets the drifts in a couple of hundred feet, to find rock that a look at will banish the blues.

NEW HOISTING WORKS.—Pothill *Tidings*, February 13: The new hoisting and pumping machinery being put up by the Orleans Company on the Wheel Betsey mine, will be ready

to start in a very few days, and is said to be of capacity to go down 1,200 ft if necessary. This claim is believed to be a good one, and the company seem determined to bring its light out from under the bushel.

The oldest mine now being worked in this district is the Empire, better known as the Opbir. It has had its ups and downs for over twenty years past; sometimes gaily prosperous, at others only fairly so; again hardly paying expenses, and several times so long under a cloud that it was thought the pumps must come up and the works be abandoned. Pluck, however, carried it over every rifle, and to-day it is one of our best mines. Last month the yield was \$22,000, and appearances underground are said to justify the expectation of its continuing a paying property for years to come. Owners of other mines, once prominent, but now idle, and, while idle, worthless, should profit by the example of the Empire and push ahead their works.

PLACER COUNTY.

A BONANZA.—We understand that a genuine bonanza has been struck at the Green mine. The old pay chute, from which about \$80,000 was realized above the 100 ft. level, when the mine was being worked some two years ago, has been struck in the drift, at a depth of some 300 ft, and the rock is as rich as ever. The rock taken out now is, from what the miners say, beautiful to behold. The new steam mill, at the mine, is fast approaching completion, and when it gets in operation on this rich rock we may look for some of the bright old cleanups that characterized this mine in the days of its youth.

BOOTH MINE.—On a short visit to this mine, yesterday, we were happily surprised to note the great improvements that have been made on the works recently, and the way the work is being pushed ahead under the supervision of R. E. Meyer. The rich character of the rock which the mine has produced and is producing, considered in connection with the width of the ledge, and the great breadth of the pay chute, which latter is already developed to the extent of about 200 ft, makes this, almost without exception, the most promising young mine in the country. The main shaft is down about 135 ft, and the most encouraging feature of all, perhaps, is the fact that the deeper they sink the better is the quality of the ore. An assay of rock from the bottom of the main shaft, made a short time ago, went \$86 per ton. A new winch has recently been erected for hoisting. Just now, besides stopping rock from between the two shafts above the 65-ft. level, to keep the mill running, a force of men is engaged in driving the west drift, and another force in sinking the main shaft. As fast as the rock is taken out it is hauled to the Eclipse mill and crushed. The mill is running now on rock from the slope above mentioned, which is turning out from \$25 to \$30 per ton.

SONOMA COUNTY.

LOCAL MINING ITEMS.—Russian River *Flag*, Feb. 11: Four tons of ore from the Georgia, reduced in the Missouri's retorts, yielded 7 flasks of quicksilver, which is about 15 per cent.

The new owners of the Socrates have 60 men at work at the mine.

A SILVER bearing ledge located about two miles from Pine Flat, between the Sausal and Calistoga roads, is attracting considerable interest in town. Assays of the rock show the precious metal in paying quantity. The mine is named the Humboldt, but its supposed richness has caused it to be spoken of as the "Bonanza," by which name it is more familiarly known. The owners are A. Wright, H. K. Brown, R. Gilbride, P. W. Sterling and Thos. Smith. Some of the ground has been sold for \$1 per foot.

There are 20 men at work on the Occidental. One tunnel is in 70 feet, another 40 and another just begun. A railroad has been put in the main tunnel.

Nevada.

WASHOE DISTRICT.

OPHIR.—Gold Hill *News*, Feb. 11: The mine is looking splendidly throughout. All the ore breast and stopes from the 1300 to the 1465-ft levels are looking splendidly and yielding the usual amount of rich ore. Sinking the north winze on the 1465-ft level is making good headway, the bottom still in ore of the richest possible character. A cross-cut has been started on the 1700-ft level, to determine the value of the ore vein in that portion of the mine. The Mexican north drift on the 1465-ft level is showing improvement. Work progressing well at all points.

IMPERIAL-EMPIRE.—Driving south along the west wall of the ledge on the 2000-ft level, to connect with the bottom of the winze for air purposes is making good progress.

DAYTON.—The face of the main south drift on the third station level is in quartz and ore of a very fine character.

SIERRA NEVADA.—Sinking the new shaft is progressing finely, the rock in the bottom working quite soft.

GOULD & CURRY.—Driving the north drift on the 1700-ft level is steadily advancing to meet the south drift from the winze on the Best & Belcher line.

SAVAGE.—Preparations are being made for soon opening the 2200-ft etation, and starting a drift to out and prospect the ore vein on that level.

CALIFORNIA.—Cross-cut No. 2, on the 1500-ft level has penetrated exceedingly rich ore within the past two days. It is now in this ore between six and eight feet, and the character of the ore is such as to show conclusively that the

main bonanza has now been reached. It is the richest description of black sulphuret and chloride ore, and assays well up in the hundreds. The drift running north from crosscut No. 1 is also in ore of the same character, and of the same great value. Crosscut No. 3, to the northward on the same level, is passing through low grade ore, but is not far enough east by 20 or 30 feet to cut the rich ore found in crosscut No. 2. In due time the rich ore will, undoubtedly, also be reached at this point.

CONSOLIDATED VIRGINIA.—The new C. & C. shaft is down 200 ft., the sinking making rapid progress. A portion of the new hoisting machinery for this shaft is being received on the ground, and will be erected, ready to take the place of a donkey engine now used for doing the hoisting, as soon as a sufficient depth is reached to render the present light machinery of no further avail.

BELOCHEN.—Daily yield, 450 tons of ore. The ore breasts show no material change during the past week, but are all looking and yielding well. The main incline is down 155 ft. below the 1,500-ft. level, the bottom in hard blasting rock. The north winze on the 1,400-ft. level is down 83 ft. The middle winze on the 1,400-ft. level is down 72 ft., and the south winze on the same level is down 91 ft. The bottom of all these winzes are in good ore.

WOODVILLE.—A very important strike has been made during the past few days, in the north drift, on the 300-ft. level. A body of rich sulphuret ore was struck, average assays of which give \$80 per ton, mostly silver. The main drift has been pushed ahead through this body of ore, a distance of 30 ft., and a cross-cut driven to the westward 25 ft., both of which drifts show the ore body to be well defined and of the same rich and even character. The mill is kept steadily running on ore from the mine.

SUTRO.—The face of the main west drift is still in hard blasting rock, interspersed with numerous seams of white crystallized quartz. The face of the drift is evidently approaching the main ledge found in the shaft, sunk on the hillside above, and abandoned on account of the heavy flow of water struck.

CAWON POINT.—The main incline is down to the 1,700-ft. level, and preparations are rapidly being completed for opening a new station and starting a drift at that point to cut the ore vein. The east cross-cut on the 1,600-ft. level is steadily approaching the ledge, the rock in the face working quite soft. The ore breasts on different levels show no particular change. Daily yield 450 tons of ore. The mills are kept steadily running on ore from the mine.

OVERMAN.—During the first part of the week a strong flow of water was struck in the bottom of the shaft, which has filled the mine and shaft to about 20 ft. above the 1,000 ft. station. This has necessarily caused an entire suspension of work in the mine.

JULIA.—The main south drift on the 1,000-ft. level is being driven rapidly ahead following the west lay wall of the ledge. A much stronger flow of water has been encountered which has somewhat retarded progress.

BUCKEYE.—The ledge has greatly straightened on during the sinking of the last 50 ft., and strong hopes are entertained of finding good paying ore when the ledge is reached.

UTAH.—Preparations for the erection of the new powerful pumping machinery is progressing finely.

IOWA.—It is the intention of soon commencing a new shaft for deep working purposes. This will necessitate the erection of good machinery and place the mine in a condition for a speedy and thorough development of its resources.

ORIGINAL GOLD HILL.—The main south drift is going ahead in fine ore indications. Another cross-cut is being made from the main north drift, which is in ore.

LADY BRYAN.—Cross-cut No. 3, on the 180-ft level, has shown a fine improvement in the character of the ore penetrated. Average assays of the ore give \$50 per ton, mostly silver, and the ore shows improvement as the drift advances.

LEO.—The ledge matter in the face of the main tunnel continues of a very favorable character, carrying many seams of quartz, some of which are rich.

LADY WASHINGTON.—The important strike of rich ore just made at the 300-ft level of the Woodville, bears directly towards the Lady Washington, being undoubtedly upon the same ledge, and only a few hundred feet distant.

JUSTICE.—Connection being made at the 400-ft level with the main Justice shaft, the air circulation through the Waller Defeat section is now excellent, and that level is being actively developed.

PHIL SHERIDAN.—The winze below the bottom of the main west drift makes good progress, with a little water coming in. It is sinking in the ore streak developed by the tunnel, and some very good assays are being obtained.

UNION CONSOLIDATED.—The face of the northeast cross-cut is still in ledge material of a very favorable character, with strong seams and streaks of quartz and low grade ore.

GENESSEE No. 2.—Some good looking streaks of quartz are being met with at present at the bottom of the shaft, some of them carrying metal.

JACOB LITTLE.—Both west drift and cross-cut are showing finely and bid fair to soon develop a good paying body of ore.

WELLS FARGO.—Sinking the main shaft is making fine progress, with strong indications of soon reaching the ore vein.

MEXICAN.—The north drift on the 1465-ft level is driven rapidly ahead, with a steady improvement in the quality of the ore.

(Continued from Page 114.)

some experience, to \$7.50, and, in rare cases, even \$10, for remarkable experience or unusual success. One may set the average at \$2.50.

CONDUCTORS—On horse cars, \$2.50 a day for from 14 to 16 hours. On steam cars, from \$3 to \$5, according to experience, responsibility and kind of service.

COPPERSMITHS—\$3 to \$4 for each work as pipe, stills, tanks, vats and kettles.

DRESSMAKERS—\$10 a week in shops; those who go to the houses of their employers receive from \$2 to \$3 a day and board.

DRIVERS—On horse cars \$2.50 a day for from 14 to 16 hours. Drays and trucks, \$2.50 to \$3 for 10 hours. Express and delivery wagons \$1.50 to \$2.50, and found. Coach and hack-drivers, \$1.75 to \$3, and found.

EDITORS—Those who are also proprietors, and manage their own affairs, have incomes not to be commonly known, or at least generally stated. Employed editors, local, commercial, etc., receive from \$100 to \$250 a month. A few surpass the figure, but not a sufficient number to seriously affect the average already stated.

ENGINEERS—For stationary engines, in mills and mines, wages range from \$2.50 to \$5 a day. On railroads, from \$3 to \$4; on steamboats and steamships, from \$2.75 to \$5.

ENORAVERS—Generally work by the piece. When employed upon salary they receive from \$4.50 to \$6. In cases of remarkable skill or of unusual urgency they command as much as \$10 and even \$12.50 a day.

FARMERS (OR RANCHERS)—This year farm hands are getting an average of about \$35 a month, with board. During harvest they receive \$40, \$50, and even \$60. This is lower than the average of former years.

FLORISTS—\$40 to \$50 a month and board. Flowers grow so naturally here and, consequently, require so much less care, that florists' wages are relatively lower than one might, at first thought, otherwise expect.

FOUNDRYMEN—Workers in iron command from \$3.75 to \$4. Some extra skillful molders get \$5; core makers, \$3.50 to \$4; stove mounters, \$3 to \$3.50. Workers in brass, cupola or furnace tenders, \$3 for 11 hours; molders, \$3 to \$3.50 for 10 hours; and finishers, \$3 for 10 hours.

GARDENERS—From \$45 to \$60 a month, with board, or from \$2.50 to \$3 a day for short jobs; the constancy and fineness of the climate rather work against them as against florists.

GAS-FITTERS—From \$30 to \$50 a month and found. Generally work nine hours a day in the shop.

GILDERS—\$3.50 to \$5, rising, in rare cases, to \$7.50.

GLAZIERS—\$2 to \$3.50 a day; occasionally \$4. Usually rank with painters.

HARNESSE-MAKERS—\$2.50 to \$5; average about \$3. Commonly classed with saddlers.

HATTERS—Command \$4. Those here are very skillful, but their number is not great.

HOTELERS—From \$30 to \$40, in large livery and horse-car stables, to \$75 and even \$100 in the private stables of wealthy citizens.

JEWELERS—\$3.50 and \$4 to \$5; diamond setters get from \$6 to \$7.50.

LAUNDRYMEN—\$30 and \$40 a month and board; women, the same. These are the rates in large laundries. In private families, women get as high as \$40; more commonly, \$25.

LITHOGRAPHERS—Draughtsmen and engravers, \$5 a day for eight hours; printers, \$4 for same time.

MACHINISTS—From \$3.50 to \$4 for from nine to ten hours. In some mills or factories, \$5.

MASONS—\$4 and \$5; foremen, \$6 to \$7.50.

MILLINERS—\$1.50 to \$2.50. Many work by the piece, and make from \$2.50 to \$4.

MINERS—In this calling, also, the extreme diversity of occupation from the merely manual labor of coal-mining to the higher and more scientific branches of gold, silver and quicksilver extraction, is so great that one can safely give no general average. Wages range all the way from \$1.50 to \$2 a day for sinking shafts, running tunnels, timbering, etc., to \$3, \$4, \$5 and even \$7.50 a day for running retorts, superintending amalgamators, separators, stamp-mills, etc. The general superintendents of some of the richest mines get from \$250 to \$500 a month, and the last figure is by no means the highest limit.

MODEL OR PATTERN MAKERS—\$4 a day. When working by the job or piece, from \$5 to \$7.50. As a rule, all over the city, pattern makers belong to the engineers' or machinists' department, and, hence, work the same number of hours a day. Boys generally start at \$2.50 a week.

MOLDERS—Loam molders for dry castings, \$5 a day; green sand-molders, \$4.

NURSES—First-class female nurses readily command from \$15 to \$20 a week. The former price is the more general.

OPERATIVES OR MILL-HANDS—Cotton factory: As the entire State contains but

few cotton factories, and those working upon a limited line of goods, there is no general demand for operatives. At present the wages average very nearly the same as those paid in the woolen mills, as subjoined:

Woolen Mills—Sorters or graders, \$2.50 a day of eleven hours; carders the same; foremen in both departments, \$4 to \$4.50; card tenders, all Chinese, 90 cents; spinners, \$2.50. In this department most of the work is done by self-operating machines, tended by Chinamen or boys at 90 cents.

Weavers—Same as spinners. Loom fixers and tenders \$2.50 to \$3.

Finishers—Four or five white men get \$2.75.

In nearly all these departments Chinamen do almost the whole, and receive the uniform price of 90 cents a day of 11 hours. Foremen in each department average \$4.50 a day.

PAINTERS—Carriage painters, \$4; house painters, \$3.50; ship painters, \$3; and sign painters from \$5 to \$15. Plain lettering brings 12½ cents a foot; gold lettering, on glass, \$1 a foot.

PAPER-HANGERS—Commonly work by the job; when paid by the day, they rank with house painters and get the same wages, \$3.50.

PIANO MAKERS—Are very few; they commonly rank with cabinet makers, getting an average of \$4 or \$4.50 a day.

PIANO TUNERS—\$2.50 for each instrument, or \$5 a day when employed at regular wages.

PLASTERERS—Generally rank with masons, and command \$4.50 a day.

PLUMBERS—\$4 to \$4.50 for nine hours, though ten hours is fast becoming their standard, as it is, generally, in most mechanical or industrial pursuits.

POLICE—Patrolmen \$125 a month.

PRINTERS—Job work \$3.50 to \$4; foremen, \$5; boys, \$1 to \$2.50. Ruling rates per 1,000 ems range from 50 to 60 cents.

REPORTERS—Ordinary reporters, writing long-hand, receive from \$15 to \$40 a week, according to experience and ability; a few get \$50. Phonographic reporters get from \$5 to \$10 a day, or a case, for reporting, and from 15 to 25 cents a folio for transcribing.

ROGERS—\$4 for nine hours; over-time or Sunday work, 75 cents an hour. Foremen, \$5.

SADDLERS—Quite variable, ranging from 2.50 to \$5; averages about \$3.50.

SAIL-MAKERS—From \$3 to \$4 for 9½ hours, in the loft. Outside and job-work, from 10 to 30 per cent. higher.

SAILORS—For long sea voyages, able seamen get from \$25 to \$30 a month. Outside coasters, \$40; and inside or boy sailors, who have to load and unload, more frequently, \$45. Third mates from \$40 to \$60; second mates from \$55 to \$75; first mates from \$60 to \$90; captains from \$75 and \$80 to \$150, and even \$250.

SALESMEN—From \$2 to \$5, according to the kind of business, and the experience and success of the party. They are quite frequently employed on commission.

SECRETARIES—The vast number of mining and other companies in California employ a small army of secretaries, who receive from \$100 to \$300 a month. Some act in a similar capacity for from three to six, eight, and even ten smaller companies.

SERVANTS—For general housework, get all the way from \$15 to \$25 a month, and board.

SHIP CARPENTERS—\$4.50 for from nine to nine and a half hours. Taking the year through, the ship-carpenter, in consequence of the weather, cannot work quite as steadily as the ship-joiner, hence, his wages are a fraction higher.

SHIP JOINERS—\$4 for same time as the ship-carpenter. In some cases their wages are equal, but, generally, the difference is as above stated.

SHOEMAKERS—Readily earn from \$2 to \$4.50 a day. The varieties of work are so great that it is almost impossible to give a general average. They generally work by the piece, or job, so that their wages depend upon their own skill and diligence.

STEVEDORES—\$2.25 for nine and a half hours. Transient work, or irregular jobs, \$2.50.

TAILORS—Generally work by the piece. For pants, they generally get from \$3 to \$5; vests, \$2 to \$4; sack-coats, \$6 to \$10; frock-coats, 10 to 16; over-coats, about the same as for frock-coats.

TEACHERS—In public schools, command all the way from \$45 to \$200 a month, according to work and position. In San Francisco, female teachers average \$75 a month, for twelve months in the year, while a few lady principals get \$150, \$175, and even \$200 a month. This is much higher than they receive anywhere else in the world, and accounts for the very great excess of the supply over the demand. Male teachers get from \$100 to \$200; only three rising above the latter figure, two of whom have \$250, and one \$225. This is, relatively, considerably lower than male teachers of corresponding schools receive in several of the larger eastern cities. San

Francisco is the female teachers' pecuniary paradise. In the smaller cities, and through the country generally, salaries range from \$40 to \$80, for female, and from \$60 to \$150 for males, and are paid during but nine or ten months of the year.

TEAMSTERS—Average from \$35 to \$60 a month, where the employer finds the team. Some of the larger city corporations pay their teamsters \$70 and even \$75, and furnish the team. Where the teamster furnishes the team himself, he gets from \$2.50 to \$4 a day.

TINSMITHS—From \$3 to \$4 for from nine to ten hours' work; generally the latter.

TRUNK-MAKERS—Average about \$3 a day.

TURNERS—In wood command about \$3.50. In ivory and metal, the rates are from \$4 to \$4.50.

UPHOLSTERS—Receive from \$4 to \$6. As one might infer from the wages, the demand for them is good.

WAITERS—In hotels, restaurants, saloons, and in private families commonly average \$45 and board.

WATCHMAKERS—Until the present time the State has had no regular factory. While we write, however, the Cornell Watch Company, having moved their expensive machinery, and many of their most skilled operatives, from their magnificent building in Chicago, are establishing themselves in this city with such dispatch that they expect to commence regular work within a month. At present, of course, the interest involves so much of experiment in nearly all of its numerous departments, that any attempted statement of wages could be nothing more than conjectural and approximate. As early as practicable we shall present a detailed account of the multiplied industries concerned in the making of a complete watch, and the compensations which they command. At present the watchmakers of the coast rank with the jewelers, and receive the same pay.

WATCHMEN—Of whom there are a larger number than one might suppose, get an average of from \$60 to \$65 per month. Night watchmen about 20 per cent. more.

WHITENERS OR CALCIMINERS usually rank with plasterers, and get the same pay; that is, an average of from \$4 to \$4.50 a day.

The foregoing list substantially includes all the leading professions, trades and occupations. Any which do not appear will generally be found to resemble some one of those given so closely that its rate of wages may be readily and safely inferred.

The individual or occasional exceptions, some higher and some lower than the rates here given, we do not deny; we are confident, however, that anyone who will take the time and pains to average as many of each calling as the preparation of this list has compelled us to do, will hardly vary a dime from the averages we have reached.

The fluctuations, also, which especially affect the wages of many callings, make it impossible that the most carefully prepared and the most exact statement should truly record the actual fact for more than a month, sometimes hardly more than a week at a time.

Bearing these considerations in mind, we present this exhibit of our chief industries and the wages they command, as thoroughly authentic and reliable at the close of 1874 and the opening of 1875.

BOARD for common laboring men costs from \$3.50 to \$5.00 per week. For cleaner occupations and average genteel quarters the usual charge is from \$5 to \$7.50 a week. Those who wish more room, more "style," etc., can gratify themselves at from \$10 to \$16 a week. Good board and lodging at first-class hotels can be regularly had for \$15 a week, and from that to \$20 or \$25. Two occupying the same room, about 20 per cent. less.

RENT—Small tenement houses, containing four rooms, of the lower kind, situated in blocks, bring from \$3.50 to \$5 a week. Of the better class, or under separate roofs a house of four main rooms—kitchen, sitting-room and two bedrooms—with usual closets, pantry and sink-room, may be had for from \$5 to \$7.50 a week; in the suburbs of the cities, or in the country, generally, larger and better accommodations may be had for the same money, or equally good ones for less.

PROVISIONS—The present retail rates of a few of the leading articles of family food indicate the necessary cost in this vital department: Apples, 2 cts.; beans, 5 cts. lb.; butter, 40 to 50 cts.; cabbage, 1 ct.; coffee, 25 cts.; dried apples, 6 cts.; dried pears, 10 cts.; dried peaches, 12 cts.; eggs, 40 cts. doz.; flour, 6 cts.; meal (corn), 3 cts.; milk, 10 cts. qt.; onions, 1 ct. lb.; potatoes, 1½ @ 2 cts. lb.; sweet potatoes, 2 @ 2½ cts.; rice, 6 @ 8 cts.; sugar (brown), 8 cts.; white, 12 cts.; tea, 60 @ 75 cts.

This may suffice to indicate the general market. Families buying in bulk or quantities, obtain the usual reduction of from ten to twenty per cent.

FUEL—Wood, from \$10 to \$12 a cord; coal from \$11 to \$14 a ton, extra kinds commanding the usual extra rates.

CLOTHING—Good working suits for men cost from \$12 to \$20; good business suits,

\$25 to \$40; dress suits of elk X beaver, from \$65 to \$80. For women's wear our markets retail calicoes at 10 and 12 cts.; delaines, from 25 to 40 cts.; empress cloth, 60 to 80 cts.; merinoes, \$1.25 to \$1.50; poplins, \$1.50 to \$2; silks, from \$2.50 to \$5; sheetings and shirtings, 20 cts.

These statements of fact, as to actual income and necessary outgo, are based upon the supposition of only average carefulness. With unusual thrift and extra economy, any family may reduce its expenses considerably within those indicated by the figures given.

Especially in the important matters of fuel and clothing, the mildness of our climate relieves one of a large part of the expense necessarily compelled by the severity of eastern and northern seasons, especially winters.

Taken for all in all, San Francisco and California have never known a time when all the actual enterprises of the present, and certain indications of her immediate, in fact we may say of her whole future, promised as much of cheer and of comfort, when the paths to prosperity and affluence appeared more open to all, than at the beginning of this year.

Quicksilver in El Dorado.

The Mountain Democrat says:—Last week Hugh T. Turnbull brought to town and submitted to our inspection some specimens of vein matter from a four foot ledge, and slate rock from the hanging wall of the same, which he had been led to believe contained or gave indications of quicksilver. We took the specimens to F. F. Bars, jeweler, who, after inspecting them closely and submitting them to several tests, decided that the whole, numbering five or six specimens, showed strong traces of quicksilver, though none of them could be called actual cinabar. These specimens are from what is known as the Tennessee ledge, Canada Flat, about three miles south of Shingle Springs, and this ledge is an extension of the Amador cinabar ledge, recently discovered. In the adjacent ravines and surface washings Turnbull and others have frequently found quantities of smoothly washed "float" specimens of high-grade cinabar. In the minds of those who are best acquainted with the neighborhood there is hardly a doubt but that there is in the vicinity an extensive stratum of rich cinabar, the certain discovery of which will prove of incalculable advantage to the industrial and business interests of our country. Messrs. Armstrong and Hinkson, of Sacramento, and D. T. Hall, of Shingle Springs, are associated with Turnbull in the ledge which the latter is exploring, and from which the specimens above referred to were taken. They feel greatly encouraged, and apparently with good reason, to believe that they are on the right track for a valuable discovery.

About one and a half miles below their claim at Agra Peak, Sam Lane is also making explorations for cinabar with encouraging results. He has sunk a shaft 120 feet, has reached the water level, and is drifting in rock which he considers very promising. We shall wait further advices from these explorations with lively interest.

EL DORADO COUNTY.—There is a vast amount of mining done in this county; in fact it is still the predominant interest, but is chiefly carried on by close corporations, and the outside world know but little really of what they are doing, and about the only means we have of knowing that they are steadily taking out the yellow ore is their continued operations, many of them night and day the year round, and frequent receipts of coin packages from San Francisco in exchange for their dust. All those extensively engaged in mining send their dust directly to the mint, and much of the money obtained therefor is deposited at the bay, thus making it impossible to gain correct information in regard to the aggregate yield of our mines. The amount of gold taken out in a small way during the year is enormous, as any one can tell by an occasional visit to the dealer in dust. But though this interest is the present life of our county, there is nothing substantial about it—that is, this interest creates no permanent improvements of itself in the mining districts. The money thus obtained does not, or has not heretofore gone toward the permanent building up of the community, as do agricultural and manufacturing industries. As we have rare advantages for all these vocations, our county being most wonderfully diversified both in climate and resources, possessing a vast area of fertile, agricultural land, vast quantities of timber, countless paying gold and silver mines, and new discoveries of quicksilver, slate, iron, copper, marble, fine whetstone ledges, etc., are being discovered; and these advantages are beginning to be appreciated. It will not be long before El Dorado county will be attracting as much attention for its superior agricultural, viticultural and other advantages, as it formerly did on account of the richness of its placer mines.—*El Dorado Republican*.

GRAVEL.—The gravel deposit at Dogtown, says the Calaveras Citizen, is furnishing some good claims. All along the channel rich gravel is being taken out. The owners of one of the claims were offered \$30,000 for their title last week, one-half cash down and the other half when taken out, but they refused to sell. Several new claims will be developed as soon as the spring opens.

Good Health.

Health and Culture.

We are in danger of becoming a nervous, uncomfortable, discontented, wretched race, unless we use our best thought and effort to bring the highest wisdom, and virtue, and order that are within our reach to bear upon our way of living. Hence the importance that more attention should be paid to the laws of health—that they should be made a study by the masses, that the principles upon which good health is founded should be taught in our common schools, and information thereupon spread broadcast by our newspapers. Hence the importance of "Health Associations" where educated men of all professions—not exclusively of the medical profession—should come together to receive and impart instructions upon this important topic.

The matter of health, in fact, should be made a part of the highest human culture, for, as recently remarked by a distinguished divine, Rev. Dr. Osgood—"Body and mind are practically inseparable, and we know nothing of the sound mind apart from sound blood and brain. I am willing to take Herbert Spencer's definition of life as the basis of our dissonance, and to allow that life is the continuous adjustment of internal relations to external relations, if by external relations we comprehend those which are social and religious as well as those which are physical. If life is the continuous adjustment of internal relations to external relations, then healthy life is such adjustment truly and fully carried out, and he is the healthy man who lives in true relations with nature, man, and God."

In this connection, we may also introduce the following remarks of Professor S. D. Gross on our sanitary deficiencies:—"As American citizens, we boast, and very justly too, of our progress in commerce, agriculture, manufacture, literature, the arts and sciences, and the general diffusion of knowledge among all classes of society, but what have we done as a nation for our sanitary condition, for those things which so vitally concern the public health, the dearest interest of every family in the land? The Government has done nothing; it has not even recognized the necessity of a great Bureau of Health, so essential in a sanitary point of view. Our local boards of health, as they are denominated, are mere shadows, the creatures for the most part of municipal authorities, who farm out our health and our lives to the highest bidder at so much a head. Surely the first, the greatest duty of a nation is to protect the lives of its citizens, by teaching them how to live, how to guard against disease, and how to improve the race. The sanitary condition of a people is intimately associated with its moral and religious welfare. People cannot be good or happy if they are not healthy. The Bible declares cleanliness to be next to godliness. Millions of people die every year from preventable diseases. Sensible men no longer ascribe the frightful outbreak of those epidemic diseases which occasionally ravage whole nations, to the wrath of an offended Deity; they know better; they know that they are due, for the most part, to man's ignorance, or man's criminal neglect?"

Bathing Children.

Some mothers think, when their children get beyond two or three years of age, the frequent entire bath can be dispensed with. If some of the main facts of physiology were well known and understood, every one would perceive that cleanliness of the skin is one of the conditions of good health. It happens when bathing is disregarded that the lungs, kidneys, or bowels have more than their own apportionment of work. If these are strong and healthy, they may bear the tax with little apparent injury, but, in most cases, a lowering of the vitality and tone of the system ensues. Large bath-tubs are pleasant and convenient, but not indispensable to the proper cleansing of the skin. A speedy sponging of the body in pure water, followed by friction in pure air, is all that is necessary. When disinclined to use water, I find a thorough application of the flesh-brush to the whole person, an admirable substitute; especially on retiring, it relieves nervousness, equalizes the circulation and induces quiet sleep. Mothers, above all, should see that their children are well bathed. If their skins are kept active and healthy, there will not be half the danger from fever, colds, and eruptive diseases. If your little one is cross or troublesome, and finds no occupation that pleases it, try the effect of a bath; sometimes the effect is magical, and if tired, he will go to sleep, and awaken bright, cheerful and happy. Do not, though, as I have seen some parents do, plunge a child in cold water when he screams and shrinks from it, thinking you are doing a good deed. Nature must be your guide; if your child has a nervous constitution, a shock of this kind is only exhausting and injurious.

COLD ON THE LUNGS.—If a cold settles on the outer covering of the lungs it becomes pneumonia, inflammation of the lungs, or lung fever, which in many cases carries the strongest man to his grave within a week. If a cold falls on the inner covering of the lungs it is pleurisy, with its knife-like pains, and its slow, very slow recoveries. If a cold settles in the joints, there is rheumatism in its various forms; inflammatory rheumatism, with its

agonies of pain, and rheumatism of the heart, which in an instant snuffs the cords of life with no friendly warning. It is of the utmost practical importance, then, to know not so much how to cure a cold as how to avoid it. Colds always come from one cause—some part of the whole of the body being cooler than natural for a time. If a man will keep his feet warm always and never allow himself to be chilled, he will never take cold in a lifetime, and this can only be accomplished by due care in warm clothing and the avoidance of draughts and undue exposure. While multitudes of colds come from cold feet, perhaps the majority arise from cooling off too quickly after becoming a little warmer than is natural from exercise or work, or from confinement to a warm apartment.—*Wood's Household Magazine.*

Cure for Corns.

A subscriber, "J. A. H.," writes from Virginia City, Nevada, as follows: "As a regular subscriber to the Press, from which I derive many valuable items of information, I wish, for the benefit of others, to speak of one which I consider has been worth more to me than the price of subscription for your paper for several years. For more than ten years I have been troubled exceedingly by corns. I was obliged to pare them as often as once a month, and had twice been to corn doctors for relief, which, however, proved to be of very transitory character. Some three months ago I saw an item in the Press taken from a French medical journal recommending peroxide of iron as a remedy. This struck me so favorably that I concluded to try it. I followed the directions, applying it morning and night with a small brush for the space of two weeks, after which I pared the tough skin away and could detect no signs of a core beneath, although before the application it could be distinctly seen every time the corn was pared. Since then I have not experienced the least pain from either of them. New flesh has formed over the places occupied by the corns which shows no disposition to harden, and from their present appearance I pronounce them radically cured. They were hard corns with cores; of its effect upon soft corns I know nothing, but our opinion is it would be just as efficacious."

USEFUL INFORMATION.

About Bricks.

Few materials for building are in more constant use than bricks. Even where stone is the principal article used in the composition of a building, bricks are wanted for linings, flues, furnaces, ovens, and a number of other purposes. The properties of bricks should vary according to the purposes to which they are to be applied. A brick intended for building should be so solid that it may be neatly cut, and baked at a temperature sufficiently high to prevent it being disintegrated by atmospheric influences. A good brick for an ordinary building will support a considerable weight without being crushed. It ought not to crumble in water nor to absorb too great a quantity of it. This question is tested by weighing the brick before and after immersion in water. Earths are often found which, without preparation, are fit for the manufacture of bricks for building purposes. Indeed, the common yellow vegetable earth will generally answer. In the construction of furnaces, the bricks to be used ought to be such as will longest resist the ashes of the combustible. Fire-bricks are made with plastic clay, containing neither gypsum, lime, or oxide of iron, which color bricks red and render them fusible. The clay is first washed to free it from the foreign substances which it contains. It is then reduced with cement of burnt clay, made expressly for the purpose, and powdered. Even the purest sand, mixed with clay, would not make infusible bricks. Bricks are formed either with the band or by manufacturing appliances. Two men, with the hand, can make from six to seven thousand bricks per day. They are burnt either with turf, coal, or wood, according to convenience, the latter being generally used in this country. The kilns are built almost entirely with the bricks intended to be burnt, the base of the kiln being the only part made of old bricks. A kiln contains about four hundred thousand bricks, and it requires about five days to burn them. The Flemish process, by which the bricks are burnt with coal, is the most economical. The manufacture of bricks in St. Louis has assumed mammoth proportions, and are becoming famous for their surpassing excellence, many persons preferring a front of them to one of stone. Milwaukee has a clay which gives a peculiar light yellowish tint to the bricks made there, which, when judiciously contrasted with trimmings of dark colors gives a very pleasing effect.—*Builders' Journal.*

WIND-MILLS.—There are said to be upwards of a hundred private mansions near New York city which employ wind-mill power for pumping water, sawing wood, grinding, thrashing grain, etc. In many instances they are superadding steam engines, water wheels, hydraulic rams, horse power, and caloric engines, being run without cost, except for lubricating oil. These mills are not only noiseless, as now constructed, but they are also self-regulating.

TO DEADEN THE SOUND OF AN ANVIL.—The *Building News* recently remarked upon this subject: "If a chain about one foot long, formed of a few large links, is suspended to the small end of an anvil, it will destroy, we are told, that sharp thrilling noise produced by striking on it with a hammer; the vibrations of the hammer are extended to the chain, which absorbs them without producing any sound. This is worth trying by any one who has a blacksmith or a coppersmith for a neighbor."

Upon the above the *American Artisan* remarks as follows: "We presume it is intended to suggest that the smith should be induced to use the chain, and not the neighbor; but with reference to this application to the head of an anvil, we may tell our contemporary that were a chain suspended in this way, the labor of the mechanic would be painfully increased; for the hammer would fall heavily and flat, without that spring or rebound that the active vibration gives to the hammer, and the brawny arm of the smith would be called upon to lift a dead weight every time he struck the iron, instead of having only to catch up the rebounding tool and direct its next blow. For our part, we think there is a very musical sound in the anvil, and certainly cannot recommend the use of the chain."

EMBALMING.—J. Hamell, of Vallée, is perfecting a process for embalming from which he expects important results. It is the result of fifteen years of study and experiment, and if we understand the principles of other embalming processes correctly, is different from any yet conceived. It differs from most methods in that no incision in the body is required. No removal of the intestines or any organs are required. The operation consists of the injection of a prepared liquid with a hypodermic syringe into the *vena cava*, and an external application of certain drugs. The effect of the process is to indurate the flesh of the corpse; making it almost as hard as marble. The features are preserved as natural as in life. In a recent case under Mr. Hamell's treatment the face had turned perfectly black; but he restored the complexion to its former color. By his method of embalming the disagreeable odor of the corpse is entirely removed. One of the bodies subjected to the conserving treatment of Mr. Hamell remained in a perfectly natural condition for three or four months. When he has further perfected his invention, he is satisfied that he can extend the period of preservation much longer.

WATER, when stored in tanks or other closed vessels, seems to undergo a sort of fining process, by which many of its impurities are thrown down as a sediment upon the bottom of the vessel. Sailors assert that water clears itself by working after the manner of wines or liquors. Though this is not strictly true, yet it is a fact that most of the impurities held mechanically suspended are thrown down and the water in time becomes fit for use.

If we can store water, exclude dust and give some time for settling, the water is pretty sure to be improved in quality. If the cistern is open there are two evils to be apprehended. Dust will find its way into the water and foul gases accumulate in the cistern. These will be absorbed by the water, and so render it unfit for both drinking and cooking. This absorption of gas by water is of much more importance than most people are aware, a very large quantity being taken up, and as the water does this with rapidity, we should not allow it to have access to foul air.

INTERESTING AND PRETTY PARLOR EXPERIMENT.—Apply a common needle to a magnet until charged, then rub dry, poise carefully between the thumb and forefinger, lay it into a tumefaction of water; if well done it will float; if it sinks try again; you will seldom fail.

No sooner is the needle afloat untrammelled when it will wheel around and point to the north pole as accurately as any mariner's compass. The tumbler can be turned around carefully, but the needle will keep its point. The common horseshoe magnet is a very interesting thing to have about a house, and can be bought for a trifle. Any common pocketknife or scissors can be charged with it, so as to draw up any small piece of iron or steel, and will retain the influence a long time.

This magnetism is a powerful element, but acts silently and unseen; one which we know the effects of, and yet know but little of its source.

AN OLD GAS WELL.—There is a gas well on Wolfe creek, about one mile from the turnpike leading from Mercer to Butler county, which was dug in 1838. This well was dug for salt, and abandoned as a salt well in consequence of a heavy flow of gas. The parties who then owned it came to Pittsburgh and had a large cast-iron cap made to cover the well, with a pipe and valve in one side. By some means they closed the valve and the salt pan and cap burst, and the works with all the apparatus was blown to pieces. Recently, Mr. Alfred Carnes, of New Castle, has leased the well, and we are informed that he is contemplating the erection of a fine flouring mill upon the premises to be run entirely with gas. It is said that gas has been flowing from this well ever since it was discovered. This information may be of use to those contemplating the utilization of natural gas permanently for manufacturing purposes.

COCOANUT husk is better than cotton waste and turpentine for taking temporary rust from iron or steel.

Domestic Economy.

Danger of Tin Vessels for Cooking Acid Fruits and Vegetables.

In a paper addressed to the French Academy of Sciences, Dr. Fordos gives the results of some experiments on tin vessels used in laboratories and hospitals, and even in private families, for infusions and similar purposes. These utensils generally contain lead in certain proportions, and it was, therefore, desirable to learn how far that poisonous metal might be injurious to health in the long run. Dr. Fordos began by introducing water acidulated with one per cent. of acetic acid into a tin can provided with a lid. After letting it stand for a few days, he observed on the inner surface of the vessel a slight white deposit, which was soluble in the acidulated water, and communicated to it all the characteristics of a lead solution; iodide of potassium yielding a yellow precipitate, sulphuric acid a white one, and sulphuretted hydrogen a black one. Nevertheless, the latter test is not reliable, since it causes a dark precipitate, with a salt of tin likewise dissolved in the liquid. The existence of a salt of lead in the white deposit is, however, sufficiently proved. It is confirmed in another way; if the inner sides of the vessel be rubbed with a piece of clean wet paper, a solution of iodide of potassium will turn it yellow. In certain experiments, a crystallized salt of lead was detected at the bottom of the jug. In other series of experiments, wine and vinegar were tried; they both became charged with lead, as they dissolved the lead salt deposited on the sides. Again, tartaric lemonade, left for twenty-four hours in the vessels, became impregnated with lead. Hence, Dr. Fordos concludes that in alloys of tin and lead both metals are attacked, the latter being generally the first, when in contact with the atmosphere and acid liquids, such as wine, vinegar, lemonade, etc.; and that consequently there may be serious danger in using such alloys, either in the shape of vessels or in tinning culinary utensils.

Bread from Sawdust.

The chief alimentary substances employed by man may be reduced to three classes, viz: Saccharine, fatty and albuminous substances, of which sugar, butter and eggs may be taken as representatives.

The saccharine principles include the majority of vegetable substances, whatever their sensible properties may be, namely: those into the composition of which oxygen and hydrogen enter, in the proportions in which they form water.

The fiber of wood is an example—it is chemically known as lignine; and by skillful manipulation Professor Anterith, of Turbingen, some years ago succeeded in making a tolerably good loaf of bread from a deal board.

The operation was as follows:

Everything which was soluble in water was removed by prolonged maceration and boiling; resinous matter was extracted by alcohol; the wood was then reduced to fiber, dried in an oven, and ground as corn, when it had the smell and taste of corn flour.

Water and yeast were added, and upon being baked it had much crust and a much better taste than bread made from bran or husks of corn.

Wood flour boiled with water furnishes a nutritious jelly; Prof. Anterith ate it in the form of soup or gruel, and in dumplings or pancakes, which were palatable and wholesome.

Prof. Brande, in his lectures, records an analogous result: "Gum and sugar may be obtained by the action of sulphuric acid upon woody fiber. Bread has been made from this substance. Seeing the close resemblance between the composition of starch and lignine, the conversion of the latter into bread does not appear so remarkable."

ORANGE JELLY.—Oranges filled with jelly is a splendid dish, which makes a pretty appearance on a supper table. Take some very fine oranges, and with the point of a very small knife cut from the top of each a round hole about the size of a silver quarter; then, with the small end of a tea or egg spoon, empty them entirely, taking great care not to break the rinds, and then throw these into cold water and make a jelly of the juice, which must be well pressed from the pulp and strained as clear as possible. Color one-half a fine rose-color with prepared cochineal, and leave the other very pale; when it is nearly ready, drain and wipe the orange rinds, and fill them with alternate stripes of the two jellies; when perfectly cold cut them in quarters and dispose of them tastefully in a dish with a few light branches of myrtle between them. Calf's foot or any other variety of jelly or blanc mange may be used at choice to fill the rinds. The colors should contrast as much as possible.

A GOOD CAKE.—Take three heaping table-spoons of powdered or granulated sugar, two of butter, one of maizeena, one egg; put with this two cups of flour, half a cup of sweet milk, a tea-spoon of cream of tartar, half a tea-spoon of soda, a pinch of salt, and Zante currants. Roll this out in powdered sugar, cut the dough in strips, and twist them as you would champagne cakes.

Among the Foundries and Machine Shops.

Business is brisk again at the foundries and
machine shops in this city and the prospects
for a very busy season are assured. The prin-
cipal work upon which they are all engaged is
mining machinery, large quantities of which
are now being made. At the

Risdon Iron Works,

Mining machinery still keeps the engineer-
ing staff employed early and late. This de-
mand has increased so much of late that they
are gradually finding the limits of their pre-
mises quite inadequate, especially as regards the
drawing and designing department, and a con-
siderable portion of this work is prepared in
more convenient quarters outside the premises.
The transportation of the heavy work in these
shops found a serious item of expense for labor
during the construction of their heavy work,
and they are perfecting a plan for doing all the
lifting necessary in the fitting and erecting
shop by team power.

The mechanical details of the new Oil Cloth Factory,

Which we recently inspected on Mission street,
show a decided improvement upon the last
new establishments of this kind in the East.
These works are supplied with capacious steam
boilers for heating and drying purposes and
producing the requisite steam for driving a ten
horse power engine. Working up the surface
of the cloth with pumice stone for coloring,
which two years ago was performed by hand
labor in many Eastern factories, is effected here
by an ingenious and simple machine.

Booth & Co.

Have lately erected a new crane for hoisting
purposes in their foundry. The design is sim-
ple and substantial, and is a serviceable piece of
work. They consider the present wet season
the slackest time in the year, but notwithstanding,
the outstanding contracts warrant a busy
time for some months to come, and they are
looking forward to a brisk spring trade. Some
heavy mining orders are at the present time in
contemplation.

The Pacific Iron Works

Are enlarging the capacity of their foundry
and raising the roof. They have also erected a
new crane, doubtless convinced of the superior
convenience of the one now in use at Booth
& Co's. This crane is now in position and the
cupolas are set up. The Superintendent is also
improving upon the arrangement of their
yard scales, which have required extensive re-
pairs of late. A very good system is being em-
ployed here in connection with making the nu-
merous plans and designs for the work.

Those youths who show most desire to im-
prove during their apprenticeship are taken
into the office and put at drawing. The Super-
intendent tells us by far the greater portion of
their work is done this way by the boys, one of

whom recently took the first prize at the Me-
chanics' Institute for mechanical drawing.

One of the neatest and best arranged of our

Smaller Machine Shops

And engineering establishments is that carried
on by Mr. Deacon, formerly in partnership
with Mr. Bulger, the present engineer in chief
at the new Mint; the latter having sold out his
share in this business on obtaining his present
position to the proprietor under whose super-
intendence these works are doing a brisk busi-
ness. The premises are not over crowded, a
rare case among similar shops at this present
day. The tools are well arranged and there is
excellent light. We noticed a substantial pair
of marine engines, of the smaller class, in pro-
cess of construction here. One striking feature
consists in casting the engine frame, cylinder,
steam chest, cross head guides and slide,
pistons and bed plate in one solid casting,
producing a very efficient body for the working
parts of the engine, and being somewhat of an
unusual method. We are able to state upon
special examination that this form of combined
casting presents no very great difficulty in pre-
paring the parts by hand and machinery, for
their exact and finished proportions, such as
boring the cylinder, planing valve seats, slide
bars and the general fittings.

A New Street Pavement.

The question of street pavements seems to be
the puzzle of the day. It is an admitted fact
that after many years of trial of cobble, wood
McAdam, granite blocks, etc., we have not yet
found a material which gives anything like sat-
isfaction to property owners. Each in turn has
been discarded, and each has again been re-
sorted to as a desperate make shift to bridge
over the present until something can be found
which shall more fully meet the necessities
of the case. Just now stone blocks appear to be
in the ascendant; but no man of experience,
in such matters, who has observed the manner
in which they are being put down in this city,
can have any confidence that they will result in
any very material advantage over the ordinary
cobble stones on streets, subjected to heavy
traffic.

Many of our citizens have taken quite a lively
interest in what is known as the "Van Camp"
patent for street paving, samples of which were
on exhibition at the late Industrial Fair in this
city, and, more lately, at No. 607, Mont-
gomery street. This is an asphaltum pavement,
composed of asphaltum and finely crushed
rock, put together with just the quantity of
spishlum which is needed to form with the
rock a firm hard cement.

This material differs in several important par-
ticulars from the so-called asphaltum employed
for making sidewalks in this city. The latter
is composed largely of coal tar, barrels of which
are poured into the tank and mixed with a small
quantity of asphaltum and small, smooth
stones, forming a compound but slightly adhe-
sive, and readily softening under the rays of a
warm sun. The "Van Camp" pavement contains
no coal tar whatever, asphaltum alone being
mixed with finely crushed rock, whose rough,
angular faces greatly contribute to the firmness
and durability of the material. The rock and
asphaltum are brought together while both are
in a heated condition so that a minimum quan-
tity of the former suffices to effect the neces-
sary cohesion.

It is well known that coal tar and its mix-
tures, when it becomes hardened, will break up
and fall to powder under the action of wheels
and hoofs, and pass away before the wind,
while asphaltum, under like conditions, owing
to its bituminous character, resists friction and
wear. The "Van Camp" asphaltum pavement
is not made in blocks but is laid down in a solid
mass five inches thick from curb to curb, form-
ing a highly resistable but slightly flexible and
continuous covering to the entire street. It is
perfectly water tight, neither contracting nor
expanding under changes of temperature, and
of course, not liable to local depressions and a
gradual breaking up, as is the case with blocks
and cobbles. It is also perfectly free from all
odor and hence especially desirable in a sani-
tary view. It is as noiseless as wood, slightly
elastic, never becomes slippery and subjects
wagon tires and horse shoes to the minimum
amount of wear.

In proof of its durability we are informed
that it has been in constant use upon one of
the principal streets in Chicago over five years,
during which time it has manifested no signs
of wear or depreciation. We are also ascer-
tained that one of the chief engineers of that city has
reported upon it in the following language: "It
has not had one cent expended upon it for repairs
since laid; shows no perceptible wear, and bids
fair to run for twenty years without repair." The
same pavement has also been laid on two
squares in Louisville, Ky., where it is giving
equally good satisfaction, and stands the sum-
mer heat in that climate without any deteriora-
tion, although it is in a locality where heavy
six-mule teams are daily passing over it. Of
course parties interested can readily verify the
correctness of the statements if they desire to
do so.

We understand that negotiations have been
completed to give this pavement a fair trial in
this city, and works have been erected near the
foot of Fourth street for manufacturing it on a
large scale. To all appearances it is all that is
claimed for it, and we are pleased to see an in-
clination manifested to give it a fair trial. We
are certainly in great need of a better pavement
than we now possess, and should be rejoiced to
see this prove the very thing that is needed.

Mechanical Schools.

Mr. A. S. Hallidie, President of the Mechan-
ics' Institute, of this city, left for the East and
Europe on Wednesday morning last. On
Tuesday evening the Board of Trustees met,
when Mr. Hallidie presented his resignation
and retired from the committee room. The
following resolutions were then read and
adopted:

WHEREAS, The President of this Board is about to
visit the Eastern States and Europe, in the interests of
the Mechanical School endowed by James Lick, and the
Chamber of Industry, endowed by Horace Hawes, and
with a view to further the interests of the next Indus-
trial Exhibition, as well as for the purpose of prop-
erly securing and forwarding the Patent Reports presented
to this Institute by the Government of Great Britain,
through his efforts to this Society, and he has verily
requested this Board to accept his resignation or grant
him leave of absence; it is hereby

Resolved, That leave of absence be granted A. S. Hal-
lidie, the President of the Mechanics' Institute, until
the first Monday in June, next ensuing; and that a copy
of this resolution be transmitted to him, signed by the
Vice-President and Secretary, under the seal of the So-
ciety,

The resignation of Mr. Hallidie was laid on
the table.

The following resolutions were then unani-
mously adopted by the Board of Managers of
the Tenth Industrial Exhibition:

Resolved, That President A. S. Hallidie is hereby ap-
pointed Special Commissioner to call upon manufac-
turers and others in the Eastern States and elsewhere,
with a view of furthering the interests of the Tenth
Industrial Exhibition, to be held under the auspices of
the Mechanics' Institute, in August, 1875.

Resolved, That the above resolution be properly en-
gaged and signed by the Vice-President and Secretary
of the Board of Managers.

Resolved, That necessary leave of absence be granted
Mr. A. S. Hallidie by this Board, for the purpose above
mentioned; and that the Board of Trustees of the Me-
chanics' Institute be requested to extend to him such
leave of absence as may be consistent with his duties as
President of the Mechanics' Institute, and the best in-
terests thereof.

After the adjournment of the Boards the
members and invited guests retired to Corin-
thian Hall, where a fine collation had been pre-
pared. Mr. Hallidie was presented with a fine
gold watch manufactured by the Cornell Watch
Company, of this city, and a general good time
was indulged in.

In conversation with Mr. Hallidie a few days
since, on the subject of his trip, he stated that
his principal object was to make arrangements
for forwarding the set of patent office reports
presented to the Institute by the Government of
Great Britain, and to examine the workings of
mechanical and industrial schools in the
East and Europe.

There are in all 3,500 volumes of these
British patent reports, of which 2,800 volumes
are imperial quarto and the balance folio. It
will take about 600 running feet of shelving to
accommodate the set. The books will be bound
in the best style, according to the require-
ments of the gift. The cost of binding will be
about \$5,000, and the books will probably be
here by the time the next Industrial Exhibi-
tion is opened.

Mr. Hallidie will also visit the leading indus-
trial schools, and with a purpose of examining
the methods by which they are carried on. Mr.
Hallidie is one of the trustees of the Lick fund
for a mechanical school, and also a trustee of
the Chamber of Industry, endowed by Horace
Hawes for a similar purpose. Several gentle-
men in this city, who are anxious that our
youth should have the advantages of an indus-
trial training, have guaranteed a fund of \$15,-
000 a year to assist in carrying out any
practical plan which may be devised; and if neces-
sary will contribute liberally towards erecting
suitable buildings for the furtherance of this
object. The Lick fund amounts to \$300,000.
The Horace Hawes endowment is not in money,
but consists of his 50-acre lot, on Mission
street, near Ninth. It will be seen from this
that there are three distinct plans for estab-
lishing a mechanical school here, exclusive
of the University of California. The only ques-
tion now is the practicability of the scheme and
the plan upon which it must be accomplished.

There are many conflicting views upon this
subject, which we are not now prepared to dis-
cuss. It is difficult to get at the exact results
accomplished by similar institutions elsewhere,
and even what information there is seems to be
conflicting. Mr. Hallidie will, during his trip,
examine into the management of the mechan-
ical schools established at Worcester, in the
East, and at Glasgow and Manchester in Great
Britain, and at Paris. It is intended to see
how such schools may be adapted to the re-
quirements of this community. The effort is
to be made to consolidate the three funds
spoken of above, so as to have only one estab-
lishment, endowed with an amount of money
to make the institution effective and practical,
instead of having three separate schools. Mr.
Hallidie states that he anticipates no trouble in
raising an amount of money sufficient to erect
the necessary buildings without touching the
principal of Mr. Lick's gift. If this is done we
ought to be able to boast of a mechanical school
which will compare favorably with those of
older cities than San Francisco.

The Trustees of these funds are desirous of
obtaining all the information possible on the
subject of labor schools, and cordially invite
those who have any practical ideas on the sub-
ject to bring their view forward for considera-
tion. If any of our readers have any plan to
propose, or experience to communicate, we will
gladly give space to their communications.
This is a subject in which all parents are inter-
ested, and should be freely discussed before any
decisive steps be taken, so that no hastily ar-
ranged plan will be adopted.

Economic Botany.

Fourth Lecture Delivered before the University of Cali-
fornia College of Agriculture on Thursday January 21,
by Prof. C. E. BESSEY, M. S., of the Iowa College
of Agriculture, Ames, Iowa.

[Reported exp. resply for the Press.]

Ths Lilies, Etc.

I call your attention, this afternoon, to sev-
eral families lying between grasses and the
conifers; that is, the lecturers to-day may be
considered as the economic botany of the re-
mainder of the endogens.

Liliaceae, the lily family, is of moderate size,
about 1,300 species. Taking the common lily
as a type, if you will group around it the
members of the order, you will have a pretty
good idea of it. Taking the lilies as a whole
(and I apply the term now to all the members
of the order), they are quite variable in their
habits, from the diminutive hyacinth to the
gigantic dragon trees. They are very widely
distributed through the temperate zones. Cer-
tain regions seem to have particular plants
which give a character to the flora represented
there. In Europe, the order is mostly repre-
sented by *Allium* and *Ornithogalum*; in North
America and Japan, by the lilies; in Mexico, by
the yuccas; in Africa, by aloes and dragon
trees, and in Australia by grass gum trees.

They are of considerable economic import-
ance, both for food and for other uses. They
furnish many medicines, most of which are
irritant, drastic and purgative, while some
furnish poisons. In most natural groups of
plants, we find some principle running through-
out all the members of the group. This may
be irritant, as in the present instance; or aro-
matic, as in the laurels; or it may be pungent,
as in the mustards. To this property, which
makes plants irritant, aromatic, pungent, etc.,
we apply the term "principle," and understand
by it that such property prevails to a greater or
less extent throughout the group. We say
then, of the order under consideration (the
lilies), that its principle is an irritant. Among
the

Food Plants,

May be mentioned the onion, *Allium cepa*, which
comes from Mediterranean basin, especially
from Egypt. It has been in cultivation for
thousands of years, probably as long as man
has lived upon the earth. Besides the onion;
the leek, garlic, hives and two or three others
may be mentioned. These are grown largely
in Europe, and are much used, especially
by the people of southern Europe. People
from the Mediterranean basin seem to make
use of the onion, rather than the people north
of that. Asparagus is a native of the shores of
southern England. As we have it here, it has a
resemblance of its old habit, growing best
where there is salt in the ground, or where salt
is applied to it. It has been grown for about
two thousand years, yet in all that time it has
shown a wonderful tenacity to its original form.
If you take up the collections of asparagus vari-
eties, you will find very little difference between
them after three or four years of poor culture.
It is one of the most remarkable examples we
have of an unmodifiable species. Within the
last eight or ten years, a few varieties have
been formed, but they very soon run back to
the original form if neglected, showing that no
true varieties have been formed.

Several of the medicines are worthy of note.
The most important are the following: White
hellebore, *Veratrum album*, which is native in
the central parts of Europe; now cultivated
throughout the continent, but most abundantly
in the Alpine regions. It has been used con-
siderably in medicine, but is less so now than
formerly; and I may say right here that for
a majority of the so-called medicinal plants the
same remark can be made, that is, that they
were formerly more used than at present, indi-
cating that we are growing

Wiser, if not Hsallhier.

Squills; the product of *Scilla maritima* is also
a native of the coast of the Mediterranean; its
bulbous roots are gathered and broken up and
in this form known as squills; which is used
somewhat at the present time as a powerful,
irritant medicine. One species of *Scilla*, found
east of the Sierra, produces a valuable food for
Indians. Here we have a good illustration
again of the fact that, occasionally, closely
allied species differ very greatly as to their
uses; the one species, in this instance, furnish-
ing irritant medicine, while the other furnishes
nutritious food. Solomon's seal, *Polygonatum
multiflorum*, is a perennial growing in England.
It is used somewhat in ordinary medical prac-
tice, and is said to be in great repute for re-
moving discolorations of the face, produced by
blows. Aloes, derived from a plant in Asia-
and a few others—are used somewhat.

The order is of most importance, however
on account of its ornamental species, which are
many, and in some cases possess exceeding
beauty and fragrance. First on the list are the
tulips; *Tulipa Gesneriana*, named after an old
German botanist, Gesner, who discovered it in
southwestern Asia and brought it into cultiva-
tion. It was introduced in 1559; so, as you see

upwards of 300 years have elapsed since its introduction. The wild plants are yellow, but in cultivation they have taken on all sorts of colors. Now and then we have a reversion to the original form. If you take up our best tulips you will find sometimes a specimen which has reverted exactly to the old form which it had three hundred years ago. As an interesting illustration of the whims of trade, the tulip mania in Holland in the last century may be mentioned as one of the most peculiar. The people became greatly excited over tulip bulbs. At that time a mania seemed to seize upon them and business was materially affected by it. The principal dealings in stock were in the stock of the tulip bulbs. They had issued scrip which represented the stock of these bulbs, and this scrip representing bulbs, was bought and sold with all the eagerness of modern stock dealers. Consolidated Virginia stock at its highest fell far below the almost

Fabulous Quotations

Of tulip stock. Single bulbs, in some cases, represented from two to three thousand dollars. Possibly there may have been a craze on bulbs when the quotations ran so high. Holland is now, as you well know, the great tulip region, and from that country we still obtain our best bulbs and probably the great interest in tulips, during this mania contributed not a little to the high development which they have attained in that country.

The lilies proper embrace many species; all belonging to the genus *Lilium*. The more important are the whitelily, *L. candidum*, from Persia; and the orange lily, *L. bulbiferum*, from Europe; the martagon lily, *L. martagon*, from Europe; the red lily, from Palestine; the tiger lily from China; the Japan lily, from Japan; and most magnificent of all, the golden lily, *L. auratum*, from Japan. This last one, produced within the last few years, a great furor in the East when first introduced. Enormous prices were paid for the bulbs, of course nothing like the prices paid for the tulips in the tulip mania just spoken of, but as much as \$50 were paid in some cases. The tuberose, *Polianthes tuberosus*, is one of the greatest favorite and deservedly so, is supposed to have been first found in tropical America and is much esteemed on account of its delightful odor. The hyacinth, *Hyacinthus orientalis*, was found first growing in Syria. It was originally a blue flower but it is now of all colors. It is very largely grown in Holland and from that country we obtain our best bulbs. The red hot poker plant, a native of the Cape of Good Hope, introduced about 200 years ago, is, as I see, quite a favorite with the people of California. Nearly every garden has its plants of this species. Its winter blooming qualities render it a very desirable plant for growing.

The dragon tree, a native of the west coast of Africa, is now cultivated extensively throughout all of the warmer parts of the globe. In its native country it is very large, growing 60 to 100 feet in height, and very thick in diameter. Here it grows as a small-sized tree, having a thick stem, with a bunch of grass-green leaves at the top. Many may be seen in the city of San Francisco and also in the streets of Oakland. The largest one on record grew upon the island of Teneriffe. It was 16 feet in diameter and was supposed at the time of its overthrow, in 1867, to be

The Oldest Tree on the Earth.

Its age, as estimated by careful observers, was placed at from five to six thousand years.

Among other ornamental plants may be mentioned the crown imperial, with its circle of golden, bell-like flowers; the *agapanthus*, with its wands of pale blue flowers, which have earned for it the popular name of love flower; the sharp needled yuccas, of Mexico; the grass gum trees of Australia; the strange, leafless, thorny butcher's broom, (*Ruscus*) of Europe, and the delicate climber, the smilax of our windows. All these must be passed by, however, with a hundred others found in our grounds and conservatories. A volume might be devoted to them and still their uses and beauties would not all be described: much less then can I hope to do them justice in a part of a short lecture. The words of one who loved the flowers of Syria come now to our minds with fuller force, "Consider the lilies of the field."

The Pine-Apple Family.

This constitutes the order *Bromeliaceae*, which is confined to tropical America. It contains about two hundred species.

One of the plants is the long moss which grows very largely on the trees in the southern portion of the Eastern United States, and which is used for stuffing cushions, mattresses, and for other purposes.

The pine-apple, *Bromelia ananas*, is a native of Brazil, introduced nearly three hundred years ago into general culture. It is a spreading plant with more or less lily-like leaves; that the leaves rise from a center near the ground and spread out. From the center starts up a woody stem. These flowers usually prove abortive. The cluster changes to a form very much like that of the pine cone. Examining one carefully, you will find the remains of the old flower which have consolidated considerably with another. They seem to take very kindly to cure under glass.

Whether they are grown out of doors here I do not know. They are grown under glass as north as Chicago very extensively.

The Banana

Belongs to a closely allied family. This family is very small one, containing only thirty species, all natives of the tropics. In growing, they have the appearance of palms. View a

banana grove at a little distance and it will remind you very much of the palms. The leaves are long and spreading, and grow upon an elongated, strong stem. In fact, they may be considered as the plants uniting the lilies with the proper palms. The banana itself is called *Musa sapientum*. There is some confusion still amongst botanists as to whether plantains differ from the banana or not. They seem to be about the same as far as the specimens are concerned. Botanists have not really been able to distinguish between them. It is more than likely that they are but varieties of the same species. The difficulty arises from the fact that the plantains

one or two feet. These great, board-like leaves, are taken and used as coverings for their houses. So that, although a very little family, it is for certain regions a very important one.

The Orchids.

See Fig. 2. This family is an important one, embracing three thousand species at least. In all probability there are more in it, but these are not all known as yet. They are of various habits, of wide distribution in moist regions. All the orchids, you will recollect, as being lovers of moist localities. In the north, they are found growing in bogs and wet places. As

Fig. 2. An Orchid (*Lelia*).—From a Specimen in Dr. Gray's Conservatory.

and bananae were cultivated for ages before botanists found them; and it is now impossible to say whether they were originally distinct or not. This is continually coming up before us in all cases of plants long under cultivation. The fruits are borne on a central spike, which grows from an enormous bud.

The flowers are about an inch and a half

you go south; you will find them in the moist forests, on the trees, as epiphytes. They are of very little economic value.

The Vanilla.

Vanilla planifolia is of vine-like habits, and is a native of the West Indies and of Central America. It grows inconspicuous flowers, which produce the long pod from which we get the extract we call vanilla. This product, vanilla, when pure, is said to be the most costly vegetable product we have. It sells at enormous prices. It is very frequently adulterated, as is commonly the case with high-priced products. The chemists, too, have been able to imitate vanilla so closely that their article is frequently used as a substitute for the genuine. When first carried from Central America to India, to be there grown, it was found that while it grew well and produced flowers, it would not produce fruit. This was, for many years, a puzzling thing to the growers; but after a while it was discovered that in Central America the flowers were fertilized through the agency of a certain insect, and that in carrying the vanilla plant to India, this insect had not been taken along with it. When, however, the insect was taken to India, the vanilla there grown became fertile and produced fruit. The history of this plant may teach us, that what now seems to many merely a curious investigation—I refer to the relation existing between insects and plants—may turn out to be of great practical importance. Aside from the vanilla, orchids are chiefly interesting as ornamental plants and as botanical curiosities.

The Palm Family,

For the inhabitants of certain portions of the torrid zone, is just as important to them as the grasses are to the inhabitants of the temperate regions. Now, we here get certain ideas of the relations existing between man and the vegetable kingdom. There are a thousand species, some of which rise to a very great height, and their usual habit you are very well acquainted with. They grow with a tall, cylindrical stem, with a great tuft of leaves at the top. In their growth, many of the palms remain stemless for a long time. They first grow a great tuft of leaves for a great many years from an underground stem. This tuft grows larger and larger, and a great, stout stem, when it is large enough, shoots up. They seem to have a beautiful and almost divine loftiness. After they have gone up a certain height, they appear to have fulfilled their mission, and die.

The double coconut (see Fig. 3), found in the islands of the Indian ocean, grows to be about a hundred feet high, with a stem from one and a half to two feet in diameter. It bears nuts in great abundance, usually from eight to nine or ten in a bunch, in this way: each nut will weigh from thirty to forty pounds, so that there is a bunch weighing from three to four hundred pounds. A very remarkable thing is that they are

Ten Years in Their Ripening.

It seems strange here where we are accustomed to see fruits ripen in one year, or less, to think of a fruit requiring ten long years for its ripening process. The natives use coconuts in various ways, utilizing the stems, trunks and leaves of the trees, as well as the

Fig. 3. The Cocoa-Nut Palm.

long. The bud goes on growing constantly, and the fruits begin forming below, so you may have a bud at the top, and fruit growing at the bottom.

This banana is one of the most productive of all plants. The statement of the books is that where thirty-three pounds of wheat can be grown, upon that area

4,400 Pounds

Of bananas could be grown. You know from your own experience that bananas are very nourishing. They will go, perhaps, fifteen or twenty times as far as the wheat grown from the same area. In countries where they are grown readily, the inhabitants subsist almost entirely upon them.

Not only do they obtain food from them, but they make use of these enormous leaves, ten or fifteen feet in length, and having a breadth of

nuts. The nuts themselves, by the time they ripen are entirely insidible. The coconut proper is a native of tropical Africa, India, Malay and all the tropical islands of the Indian and Pacific oceans. It is generally cultivated in all the islands of the tropical regions. The trees are from fifty to one hundred and fifty feet high. It produces fruit in bunches of from ten to twenty each. The tree furnishes almost everything the inhabitants need. They have not very many wants. From it they get food, domestic utensils, materials for building, wine and sugar. From its principal fiber they manufacture ropes, matting, brushes and brooms. The stem yields very valuable lumber. So it will be seen, the tree is of very great importance to the people.

The sago palm, *Sagrus laevis*, is found in Siam and the Indian archipelago, and grows from thirty to fifty feet high and six to twelve inches in diameter. The tree is cut and the trunk is split, the pith is then taken out, thrown into water, and upon beating it a starchy matter falls to the bottom; this is the sago known in commerce, and is used very largely as an article of food. A student says: "Then they have to kill the tree to get this." Professor: "Yes. They have to cut it down and of course, it results in the destruction of the tree."

Rattan, *Calamus rotang*, and other allied species, natives of India and the Malay islands, produce the rattan, so largely used in the manufacture of chairs and other furniture. These are slender-stemmed palms, often growing to a length of from 150 to 200 feet, and climbing by their leaves—which have retrorse prickles upon them—over high trees and rocks.

There are a great many other palms which we have not time to notice. We must pass by with but a mention, the date palm of the deserts of Africa and Western Asia; the wax palm, of South America, from whose wax, holy candles are made to be used in the cathedrals of New Granada; the ivory palm, of tropical America, whose nuts become as hard as ivory, for which they are largely substituted; the climbing palms, of New Granada, whose long, tough stems are there twisted into cables and used in making suspension bridges; the cabbage palm, of the West Indies, whose young unexpanded leaves furnish a succulent food not very unlike the cabbage; the betel palm, of Cochinchina, which produces the far-famed betel-nut, so largely used by the inhabitants of the Indian ocean, in the way that more civilized people use tobacco; and the various palms which produce "toddy," which may be considered to be the whisky of the palm countries. You see then that this family of the palms, while not strictly of so great interest to us, is a most important one for the inhabitants of the warmer regions of the globe.

NEW MAP OF THE COMSTOCK.—J. B. Treadwell, U. S. Deputy Mineral Land Surveyor, has just issued a new map of the Comstock lode. It represents a number more locations than maps previously issued of the Comstock and is of convenient size. It is drawn on a scale of 1,000 feet to the inch and is 30 by 36 in size, mounted on rollers. It gives a longitudinal section of the lode with shafts, representation of ore bodies, etc. The shafts are all carried down to the depth at which they were when the map was issued—about the first of this month. The map was compiled by Mr. Treadwell, from patents, plats in the Land Office; drawings at the mines, and surveys by himself. Many of the locations which are not incorporated are shown on the map. The size of the map is much more convenient for office use than those published drawn on a larger scale, and it is published at the low price of \$6.

THE Consolidated Virginia mine is yielding 400 tons of ore per day. The ore breasts throughout the entire mine never were looking and yielding better than at present. The Gold Hill News says that the mine is simply looking magnificent at all points, all the prospecting drifts and winzes being in the richest character of ore. The mills are all running on ore from the mine, and are kept working to their fullest capacity. The yield for the past month was \$1,001,500, and notwithstanding the present will be a short month, it is confidently expected that the yield will be increased to between \$1,200,000 and \$1,400,000.

PAINFUL ACCIDENT.—James Hill, Esq., U. S. Boiler Inspector, was thrown from his buggy one day last week, and fractured his right leg between his ankle and his knee. This will probably prevent his attending to the duties of his office for a month or more, during which time C. C. Bemis and Captain Waterman will attend to all matters requiring the attention of the Boiler Inspector.

At the Poorman mine, in Idaho, the Burleigh drill are doing very well. The drills and compressors have been at work there about three months. By hand labor the progress in this shaft was twenty inches per day. With a Burleigh drill they now make six feet. The cost of making six feet is just the price of a quarter of a cord of wood above the cost of sinking twenty inches.

At the New Almaden quicksilver mine, San Jose, with the Burleigh drill, 177 feet of tunnel, 8x8 in size, was made in January, against 33 feet made by hand labor the previous month, cutting a tunnel but $4\frac{1}{2}$ x 6 feet in size.

The numerous mines in the vicinity of Ogden are being developed with much vigor, and are said to be looking finely.

BALL'S

SWEEPING DREDGE,
A NEW AND VALUABLE.

CALIFORNIA INVENTION,

Has been very lately well proven by performing a job of dredging at the mouth of San Antonio Creek, at Oakland, Cal.

There is but this one machine that has ever had these improvements employed. It is an old machine, formerly built for another device, and is unfavorably constructed for Ball's improvements; yet this first temporary experimental machine has filled a scow of eighty-five cubic yards in sixteen minutes in unfavorable digging. For durability, digging hard material and fast work, it has a reputation (supported by leading engineers) as having no equal.

Testimonials and references will be given on application to the inventor, who is the sole owner of patents (excepting having made an assignment of the one machine now belonging to the Central Pacific Railroad Company) Having resolved not to sell any rights unless upon a basis of actual work performed by a machine built by myself for the purpose of fairly establishing the worth of the invention, I therefore offer to sell machines or rights on the following plan, which is warranting the capacity of the machine by actual work:

I will enter into an agreement with any responsible party to build and sell a machine, scows and tender, all complete, and right of all my improvements in dredging machines throughout the Pacific Coast for \$20,000, warranting the machine to dredge six cubic yards per minute (to fill a scow at that rate). \$20,000 will but little more than pay the cost of building the machine, scows, etc., all complete; therefore I am proposing to ask nothing for my patents unless my machine dredges more than six cubic yards per minute. But it shall be further agreed that in case (at a fair trial to be made within a stated time) the machine shall fill a scow at the rate of more than six cubic yards per minute, then \$10,000 shall be added to the price above stated for each and every such additional cubic yard thus dredged per minute, and for additional fractions of a cubic yard thus dredged in the same ratio the \$10,000 is to be added to said price above stated.

I will sell any other Territorial or State rights (either United States or Foreign) upon the same plan and at a lower price proportionately than the rights for the Pacific Coast.

I will sell a single machine with scows and all complete, and right to use the same in a limited territory, for \$20,000 on the same plan as above stated, but will add only \$2,000 to each additional yard over the six cubic yards per minute. Each machine is not to employ more than two 10x20 inch engines.

Payments to be made in U. S. gold coin on delivery of machine, as may be indicated by agreement.

Address, **JOHN A. BALL,**
9v28-1f Oakland.

JOHN TAYLOR & CO.

Varney's Patent Amalgamator.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be spared to have them constructed in the most perfect manner and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits. They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows.

The pan being filled, the motion of the muller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Settlers made on the same principle excel all others. They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill-men are invited to examine these pans and settlers for themselves, at the office, 229 Fremont Street, San Francisco.

TEATS' PATENT FURNACE.

TEATS' PATENT FURNACE

For Roasting, Desulphurizing, Chloridizing and Oxidizing Ores, etc. For the reduction of Gold, Silver, Lead and other ores, saving a larger percentage, at less cost, than any other invention now in use. Chloridizing Silver ore more thoroughly, in less time, with less fuel, salt and labor; also roasting Lead ore preparatory to smelting, better and cheaper than any other invention. The Furnace is so constructed that one man, of ordinary ability, tends five or more furnaces, controls them with ease; adding heat or air; stopping or starting at will; charging and discharging with ease. Also, Patent "Conveying Cooler," for conveying and cooling roasted ores, heating the water for amalgamation and the boilers at the same time. Saving the large space in mill (covered with brick or iron), and the labor of two men per day, exposed to the poisonous chlorine gases. Also, Patent Air Blast "Dry Kilm," for drying ores direct from the mine or breaking, saving fuel and labor heretofore necessary in drying ores for dry pulverizing. For description refer to MINING AND SCIENTIFIC PRESS, No. 18, October 31, 1874. For particulars address

D. B. MILLER & CO.,

No. 12 West Eighth Street, Cincinnati, Ohio Circulars, &c., will be furnished, if required. 18v29-3m

CROCKER'S PATENT

TRIP HAMMER QUARTZ BATTERY.

This machine, complete, weighs 1,500 lbs. Has an iron frame, five-steel arms with clamps working 17 lbs. each, which strike 2,000 blows per minute, in a mortar provided with screens on both sides, and crushes FINE 800 lbs. per hour, requiring one-horse power to drive it. Has been thoroughly tested, and is guaranteed to give good satisfaction. PRICE, \$500.

G. D. CROCKER,

17v26-4f 315 California street, San Francisco,

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s MINING AND SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

CUTTING ATTACHMENT FOR SEWING MACHINES. M. A. Graham, San Francisco. This is an attachment for sewing machines which consists of a shear cutter so arranged as to be operated by the movement of the needle arm. An adjustable guide is fitted to regulate the width of the material to be cut. This device is extremely useful for cutting the trimming which is used in narrow strips in large quantities for ladies' dresses and it can be made with great rapidity by simply running the machine at a considerable speed.

COAL OIL STOVE. B. R. Sweetland, Sacramento, California. This invention relates to improvements in that class of coal oil stoves in which a water chamber is introduced between the oil reservoir and the point of combustion for the double purpose of keeping the oil tube cool and applying elements of combustion to the flame. The improvement consists in a peculiar arrangement of the water chamber, by which a more extended water surface is presented for vaporization, and at the same time the difficulty is avoided which has heretofore been encountered by the enlargement of the toothed wheels which raise and lower the oil wicks with the water wicks. It also consists in combining with the external water surface a heat radiator which will concentrate the heat upon the water and increase the evaporation.

FASTENING SEAMS IN OVERALLS. Chaug Quon Wo, San Francisco. This improvement in overalls consists in forming a gusset or triangular lap upon the piece of goods which comes opposite the corner of the pocket or other termination of a seam, and then sewing the lap or gusset down across the seam. The small lap which is shaped when cutting the material, is lapped over the corner of the pocket or seam and sewed down firmly all round so that it will form a gusset for strengthening the corner of the pockets and prevent them from ripping or being torn by any ordinary strain that may come upon them. The small lap spoken of is formed in the proper place when cutting the cloth for the pants so that it forms a permanent part of one of the pieces of the pants and is, therefore much stronger and more durable than if it was a separate piece sewed over the seam. This is the first United States patent, we believe, ever issued to a native of China.

CURING TOBACCO. Sebra R. Mathewson, Gilroy, Cal. This inventor provides an improved apparatus for hanging and handling tobacco in the leaf and stalk, in order to dry and cure it. The improvement consists in constructing a series of chains or ropes, which are formed into connected hangers and suspended upon a pulley, which moves upon an overhead rail, so that by moving the pulley along the rail the entire hangings with their loads can be shifted easily from place to place without handling the leaves.

ELASTIC DEMIJOHN. Carlton Newman, San Francisco, Cal. This is an invention which we described in detail on the 19th of September last, but the patent was only issued in January. It consists in surrounding the bottles with an elastic jacket, and weaving the rattan around the covering, thus doubly protecting the bottle. This patent demijohn is having a large run and meeting with ready sale. They will probably entirely supersede those of the old style. Mr. Newman has ten men constantly at work on these demijohns at the San Francisco glass works, where they are made exclusively. This is another use to which that abundant material, tule grass, is put, as Mr. Newman uses this as a covering for the bottles, on account of its superior elasticity and its cheapness.

DITCHING AND EMBANKING MACHINE. Wm. B. Hyde, Oakland, Cal. This invention relates to an improved machine for excavating shallow ditches, of greater width than the width of a single mould board, and at the same time conveying the excavated earth to the outside of the ditch, so as to form an embankment either upon one or both sides of the ditch. The invention consists in arranging two or more plows diagonally to the line of travel, so that each plow will cut its furrow in the manner of a gang plow; but instead of simply turning the furrow over, each plow is provided with a wing or side scraper, which forces the earth out of the excavation and deposits it upon the brink of the ditch, where it is left to form an embankment.

In Gold Mountain district, Esmeralda county, Nevada, the difficulty of obtaining water enough for milling purposes has retarded the growth of the camp. The Borax Miner states now, however, that Mr. John Roth, has recently been running a tunnel about 300 feet in Gold mountain for water, and has made a much greater success than was anticipated, having obtained a running stream of about one inch, and thinks that by cutting fourteen or fifteen feet further through a clay wall a much larger stream will be obtained. It is probable now that a mill will be put up.

The mines around Salt Lake have swallowed up \$3,000,000 belonging to St. Louis capitalists.

General News Items.

COLD WEATHER AT THE EAST.—Last week seems to have been the cold spell of the season in the East. The cold culminated on Saturday, closing up the rivers on both sides of New York city. Large numbers of fishing vessels were ice-bound in Cape Cod bay, unable to go either in or out. The entire bay was frozen over, an occurrence never known before. A cold wave passed over Maine, New Hampshire and Vermont, on Friday night, which sent the thermometer down to 26 and 32 degrees below zero. In Chicago, the thermometer on Saturday was six degrees below zero at noon. The high wind of Thursday drifted the snow badly and caused a great deal of delay on all railroad lines. Trains on seven different roads were either unable to get in or delayed several hours. Reports from all points state that great inconvenience is experienced on account of the freezing of water-courses and scarcity of water for stock.

THE BEECHER TRIAL is still dragging its slow and disgusting length along, and all excepting a knot of the friends of the chief actors are growing tired of the repetition of the great scandal. From present appearances it is thought by some that the trial will last a month longer. Probably no trial has occurred in the last century in any part of the world which has caused so much sensation, or which presented so many plausible sides—all contrary. The parties most interested seem to be really the ones most at ease. An exchange says: Mr. Tilton laughs at the jokes, eats like a wood sawyer, takes his ride and his glass of sherry, and prepares his case every night with the coolness of a night editor getting up the day's news. Mr. Moulton takes the witness box, laughs and argues at recess, foils counsel, and is a sort of Don Cesar de Bazan in general. Mr. Beecher has a little levee every day, and sits in Court with all his family, as at a pantomime.

A FEARFUL TALE.—A mother and her eight children were burned in their house, near Montreal, Canada, a few days since. The fire caught in the lower part of the house. The father, in trying to put it out, was cut off from his family, and barely escaped with his life. The mother seized two of her children in her arms, thinking to save them and go back for the others. She might indeed have escaped with them, but the cries for help of the little ones left so overcame her, that she preferred to go back and die with all her children than to escape with a part, and she did go.

SARGENT'S LAND BILL.—The Commissioner of the General Land Office writes to the Chairman of the Senate Public Lands Committee that he thinks it expedient to pass Sargent's bill, providing that all even numbered sections, which were included within the railroad limits and afterward restored to the public domain, shall be opened to homestead and pre-emption entry the same as odd numbered sections, at \$1.25 per acre. The Committee still have the matter under consideration.

POSTAL CHANGE FOR CALIFORNIA.—Offices established at Whitesill, Mendocino county, James M. Smith, Postmaster. At Spanish Dry Diggins, El Dorado county, Wm. B. Davis, Postmaster. Office discontinued—Waterloo, San Joaquin county. Postmasters appointed—Harvey Hayne, at Stoney Point, Sonoma county.

MR. BEECHER AND THE N. Y. "LEDGER."—The announcement is made that Mr. Beecher writes no more for the New York Ledger. Whether it is Mr. Beecher or Mr. Bonner who has felt compelled to make this innovation will probably remain forever one of those problems against which the public mind rasps itself in vain.

APPROPRIATIONS FOR CALIFORNIA RIVERS.—Clayton has secured an appropriation from the Committee on Commerce of \$15,000 for the improvement of the Sacramento river. And Page hopes to secure \$10,000 for the San Joaquin river.

POMEROY, THE BOY MURDERER, TO BE SENTENCED TO DEATH.—The Supreme Court in the case of Jessie H. Pomeroy, the boy murderer, overruled the exceptions and ordered judgment on the verdict. He will therefore be sentenced to death.

THE LICK SALE.—The balance of the Lick estate will be sold at auction, at Platt's Hill, on Thursday, April 6th. The property offered includes valuable lots in this city and San Jose.

Or the forty-two millions of passengers carried over the railroads in Massachusetts last year only a single one was killed, and but seven were injured.

SETTLED.—The Santa Barbara wharf trouble, has been settled. The wharf has been repaired and steamers land as usual.

THE COMMITTEE ON APPROPRIATIONS inserted in the Indian bill \$30,000 to pay land settlers in Round Valley Reservation.

THE ANTI-CHINESE NATURALIZATION BILL has passed both houses of Congress and will become a law.

HEREDITARY CONSUMPTION BARREN.—Because there is an inherited tendency to consumption it does not follow that the heir to this sad legacy must die of the disease. The early symptoms of danger are marked—a cough being the first and most prominent. Meet this first indication of peril with *Hale's Honey of Marshmallows and Tar*, and in three days it will have vanished, and with it all cause of apprehension. No matter how delicate the lungs may be, or how strong the predisposition to consumption, a speedy cure is absolutely certain.

Pike's Tooth-Ache Drops—Cure in one minute.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington, D. C., Feb. 16, 1875.

FOR WEEK ENDING FEB. 2, 1875.*

SHOE AND GAITER.—George Bryant, S. F., Cal. **SLATE WASHER.**—Levi L. Lyman and Edward A. Boell, S. F., Cal.

SOFA BEDSTEAD.—John K. Underhill, Stanislaus Co., Cal.

SEWING MACHINE FOR SEWING BAGS, ETC.—Howard P. Garland and Andrew J. Gove, S. F., Cal.

CHAIN PROPELLER.—DeWitt C. Johnson, Redding, Cal.

APPARATUS FOR GENERATING GAS.—John H. Rawlings & Lambert Irelan, Watsonville, Cal. **COMBINED FLUTING AND SAIL IRON.**—Charles R. Rand, S. F., Cal.

EASTENING FOR METINO RAILS OF SASHES.—Chester J. Snow, S. F., Cal.

ROCK-DRILLING MACHINE.—George Atkinson, S. F., Cal.

GRAIN SEPARATOR.—Thomas J. Hubbell, Yountville, Cal.

WATER METER.—Nathaniel W. Knowlton, Nevada City, Cal.

JOINT FOR SHEET METAL PIPES.—Jos. Moore, S. F., Cal.

TRADE MARKS.

FOR TEA.—Robert Cunningham, S. F., Cal.

FOR TEAS.—Williams, Blanchard & Co., S. F., Cal.

FOR TEAS.—Williams, Blanchard & Co., S. F., Cal.

FOR CIGARS AND TOBACCO.—The Consolidated Tobacco Co., Gilroy, Cal.

The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest time possible.

To Patent Attorneys, Contractors and Inventors.

WASHINGTON, D. C. January 1st, 1875.

I have carefully prepared a complete digest of U. S. patented Paving and Roofing Compositions, up to January 1st, 1875, in which is given the name of patentee, number and date of patent, ingredients, and, (when given in the specification) the proportions of ingredients. Also, all of English Patented Paving Compositions up to January 1st, 1874, amounting in all to over six hundred patents, a complete state of the art to date. It is my intention to publish this work at an early day in book form, and should you wish to subscribe should address

L. W. SINSABAUGH, Assistant Examiner, Room 21, Patent Office, Washington, D. C.

A. ROMAN & CO.,

Booksellers, Stationers, Importers, Blank Book Manufacturers, and Wholesale Dealers in everything required by the Trade and School Departments, attention to their stock of Standard and Miscellaneous Books, which, for completeness and variety, cannot be excelled.

JUVENILE BOOKS of every description. **SCHOOL BOOKS**—Latest and most approved. **SCHOOL FURNITURE**—Elegant, durable and cheap. **STATIONARY**—Foreign and domestic. **BLANK BOOKS** in stock and made to order. **LETTER, NOTE, AND INITIAL PAPERS** in every variety.

Latest Publications received as soon as they appear. Book Buyers and Libraries supplied on liberal terms. Eastern Publishers' catalogues forwarded post-paid, on charge, upon application. Special care will be taken in filling Wholesale Retail orders by mail and express, with promptness and at the lowest cash rates. A choice assortment of the latest styles of Fine Stationery constantly on hand in both departments—retail and wholesale.

A. ROMAN & CO.,

San Francisco, Cal.

Averill Chemical Paint.

MANUFACTURED BY THE

Cal. Chemical Paint Co.

PURE WHITE, AND ANY SHADE OR COLOR.

This Paint is prepared in liquid form, READY FOR APPLICATION—requiring no thinner or dryer, and not spoil by standing any length of time. It is Cheaper, more durable, more Elastic, and produces a more Beautiful Finish than the best of other Paints.

It will not Fade, Chalk, Crack, or Peel off, and last twice as long as any other Paint. In ordering White, state whether for Outside or inside use, as we manufacture an Inside White (oil Flat or Gloss) for inside use, which will not turn low, and produces a finish equal to the finest Oil Gloss.

Put up in 1/2, 1, 2 and 5 gallon packages, and Barrels. Sold by the Gallon. For further information send for Sample Card. Price List, or apply to the manufactory and office,

Cor. 4th and Townsend streets, S. F. TYLER BEACH, M. C. JEWELL, President, Secretary.

Ayer's Cherry Pectoral,

For Diseases of the Throat and Lungs, such as Coughs, Colds, Whooping Cough, Bronchitis, Asthma and Consumption.

The few compositions which have won the confidence of mankind and come household words among not only one, many nations, must have extraordinary virtues. I have no one ever secured wide a reputation, or maintained it so long, as AYER'S CHERRY PECTORAL. It has been known to the public about forty years, by a continued series of marvellous cures, that have won for it a confidence in its merits, never equalled by any other medicine. It makes the most effectual cures of Coughs, Colds, and Consumption, that can be made by medical skill. Indeed, the CHERRY PECTORAL has really robbed these dangerous diseases of their terrors, to a great extent, and given a feeling of immunity from their fatal effects, that well founded, if the remedy be taken in season. Every family should have it in their closets, for the remedy a prompt relief of its members. Sickened, suffering, even life is saved by this timely protection. The patient should not neglect it, and the wise will not. It is by you for the protection it affords by its timely in sudden attacks.

PREPARED BY DR. J. C. AYER & CO., Lowell, Mass. PRACTICAL AND ANALYTICAL CHEMISTS.

Sold by all Druggists and dealers in Medicine.

CRANE & BRIGHAM, Wholesale Agents

729-ly SAN FRANCISCO, CAL.

Quartz Mill for Sale

At Mineral Hill, Elko County, Nevada, four miles from Mineral Hill Station, on the Palisades and Eureka Railroad, and 35 miles from the Central Pacific Railroad.

The Mineral Hill Silver Mines Company (Limited) offer for sale their new 20-stamp mill (dry crushing) built by H. J. Booth & Co. of San Francisco.

The mill is complete in every respect, with engine, Haller's Stetefeldt Furnace and all modern appliances and is as good as new, having only run two months upon ore.

The whole is offered very cheap for cash. For further information apply to

H. H. OAKES, Superintendent.

Mineral Hill, Nevada.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical House, Menagerie, Real Ponds and Skating Rink.

THE AMERICAN TURBINE Water Wheel.

Power Pledged Equal to any Over-shot Wheel Ever Built.

Recently improved and submitted to thorough scientific tests by James Emerson, showing the following effect of the power of the water utilized, being THE HIGHEST RESULTS EVER KNOWN.

Percentage of part gate, 1/2 50.08; 3/4 69.64; 5/8 78.73; 1/2 82.90. Percentage of whole gate, 83.14.

Mr. Emerson says: "These are the best average results ever given by any Turbine Wheel experience."

Amplified descriptive catalogues, or any other information desired, furnished on application to TREADWELL & CO., SAN FRANCISCO, CAL. Sole Agents for the Pacific States and Territories. 18729-cow-1f

PATENT ELASTIC PEN-HOLDER.

This Holder is furnished with a pair of elastic rubber cushions, which render a steel pen as flexible as the time goose quill pen.

It provides an easy hold, that does not cramp or tire the fingers.

It protects the fingers and desk from ink stains.

The fingers acquire a delicate touch that enables a person to obtain a beautiful hand-writing.

The elasticity of the pen can be adjusted to suit any hand, by simply sliding the pen up or down.

Sent by mail, on receipt of Seventy-Five Cents.

JOHN S. ORNDORFF, Money Order Clerk, Virginia, Nev.
